According to the process of the French Codex, this cyanuret is obtained in the dry way, without the use of any solvent. The calcination is performed in a retort, to which a tube is attached for collecting the gaseous products. When these cease to be disengaged, the heat is gradually raised to a very high temperature, at which it is kept for a quarter of an hour. When the calcination is thus conducted, the retort will be found to contain a black matter, covered by a fused layer of pure cyanuret of potassium, resembling white enamel. This is detached by means of a knife, and immediately transferred to a bottle, with an accurately fitting stopper. The black matter under the name of *black cyanuret*, is also kept for medicinal use; but the dose of this cannot be accurately fixed, on account of its containing, at different times, more or less impurity. Its filtered solution should be perfectly colourless.

Other processes have been recommended for obtaining cyanuret of potassium, which may here be briefly noticed. The process of Wiggers, which is said to excel all others, consists in passing the vapour of hydrocyanic acid into a receiver containing an alcoholic solution of pure potassa. The hydrocyanic acid is formed by slowly distilling two parts of ferrocyanuret of potassium, contained in a retort, with one and a half parts of sulphuric acid, previously diluted with an equal weight of water and allowed to cool. The acid is made to pass into a cooled receiver, furnished with a safety tube, and containing one part of pure hydrate of potassa, dissolved in three or four parts of alcohol of 90 per cent. (0.822). As soon as the ebullition slackens, the operation should be stopped; and the liquor in the receiver will be found thick from the precipitated cyanuret of potassium, mixed with the alcoholic solution of the undecomposed potassa. The precipitate is then collected on a filter, freed from the mother-water, washed with alcohol, and without being removed from the filter, pressed and dried. (*Pharm. Trans.* Dec. 1841.) The ferrocyanuret of potassium yields about a tenth of its weight of cyanuret by this process. It will be noticed here that the hydrocyanic acid is generated by the same process as that adopted for obtaining it in the last U. S., London, and Edinburgh Pharmacopœias; but instead of being condensed by itself, it is allowed to pass into a solution of caustic potassa. (See page 786.) Liebig has proposed the following process, which gives a large product of cyanuret of potassium, but contaminated with cyanate of potassa. Mix eight parts of ferrocyanuret of potassium, well dried, with three of dry carbonate of potassa, and throw the mixture into a red-hot Hessian crucible, which is to be maintained at this heat. The melted mass becomes successively brown and yellow; and finally, when it becomes white, as known by its concreting, on a warm glass rod dipped into the liquid, in a brilliant white mass, it is to be poured out into a warm porcelain capsule to solidify. Two eqs. of ferrocyanuret of iron react with two eqs. of carbonate of potassa. The iron is reduced, the carbonic acid evolved, and a compound of five eqs. of cyanuret of potassium and one of cyanate of potassa is formed. The reaction is explained by the following equation;— $2(FeCy + 2KCy) + 2(KO, CO_2) = 5KCy + KO, CyO + 2Fe + 2CO_2$. (*Pharm. Journ.*

and *Trans.*, Aug. 1842.) The cyanate of potassa may be readily detected by saturating the compound, as thus obtained, with an acid, which will cause an effervescence of carbonic acid, and the generation of a salt of ammonia.

Properties. Cyanuret of potassium is a white substance, having a sharp, somewhat alkaline and bitter-almond taste, and an alkaline reaction. It is deliquescent in moist air, very soluble in water, and sparingly soluble in strong alcohol. Its solution, when exposed to the air, exhales the odour of hydrocyanic acid. Effervescence on the addition of an acid shows carbonic acid; a yellow colour, iron; and a blackening when heated, the presence of a formiate. It consists of one eq. of cyanogen and one of potassium.

Medical Properties and Uses. Cyanuret of potassium is pre-eminently poisonous, acting like hydrocyanic acid. The tenth of a grain killed a small bird in the space of a minute; and a solution of five grains destroyed a large dog in a quarter of an hour. As a medicine it is considered applicable to all cases in which hydrocyanic acid has been found useful. (See *Acidum Hydrocyanicum*.) The grounds on which it has been proposed as a substitute for that acid by Robiquet and Villermé, are its uniformity as a chemical product, and its less liability to undergo decomposition. The dose is a quarter of a grain, gradually increased to a grain. The solution, *extemporaneously* made, is the most convenient form for exhibition, and a standard solution has been proposed by Magendie, prepared by dissolving the cyanuret in eight times its weight of distilled water. A solution of this strength is equivalent to the medicinal hydrocyanic acid, and may be prescribed in mixtures in the dose of two or three drops. A solution, made with from one to four grains to the fluidounce of water, has been recommended in neuralgic and other local pains, applied by means of pieces of linen. B.

POTASSII IODIDUM. *U.S., Lond., Ed.* POTASSÆ HYDRIODAS. *Dub.* Iodide of Potassium. Hydriodate of Potassa.

"Take of Iodine *six ounces*; Iron Filings *three ounces*; Carbonate of Potassa *four ounces*, or a sufficient quantity; Distilled Water *four pints*. Mix the Iodine with three pints of the Distilled Water, and add the Iron Filings, stirring frequently with a spatula for half an hour. Apply a gentle heat, and, when the liquor assumes a greenish colour, add gradually the Carbonate of Potassa, previously dissolved in half a pint of the Distilled Water, until it ceases to produce a precipitate. Continue the heat for half an hour, and then filter. Wash the residuum with half a pint of the Distilled Water boiling hot, and filter. Mix the filtered liquors, and evaporate so that crystals may form. Pour off the liquid, and dry the crystals on bibulous paper." *U.S.*

The London College takes *six ounces* of iodine, *two ounces* instead of three of iron filings, *four ounces* of carbonate of potassa, and *six pints* [Imperial measure] of distilled water, and proceeds as above; except that the quantity of carbonate of potassa in solution, added to the solution of iodide of iron, is taken at a fixed weight, and not left to be determined by the amount necessary to complete the precipitation, and that, after the precipitation of the carbonate of iron, heat is not applied for sometime before the liquid is filtered.

"Take of Iodine (dry) *five ounces*; fine Iron Wire *three ounces*; Water *four pints* [Imperial measure]; Carbonate of Potash (dry) *two ounces and six drachms*. With the Water, Iodine, and Iron Wire prepare the solution of iodide of iron as directed [under Ferri Iodidi Syrupus]. Add im-

mediately, while it is hot, the Carbonate of Potash previously dissolved in a few ounces of water, stir carefully, filter the product, and wash the powder on the filter with a little water. Concentrate the liquor at a temperature short of ebullition, till a dry salt be obtained, which is to be purified from a little red oxide of iron and other impurities, by dissolving it in less than its own weight of boiling water, or still better by boiling it in twice its weight of rectified spirit, filtering the solution, and setting it aside to crystallize. More crystals will be obtained by concentrating and cooling the residual liquor." *Ed.*

"Take of Iodine *one part*; Sulphuret of Iron, in coarse powder, *five parts*; Sulphuric Acid *seven parts*; Distilled Water *forty-eight parts*; Water of Carbonate of Potassa *a sufficient quantity*; Rectified Spirit *six parts*. Mix the Iodine by trituration with sixteen parts of the Water, and put the mixture into a glass vessel. Pour the Acid, previously diluted with thirty-two parts of the Water, on the Sulphuret, contained in a matrass; and by means of a tube adapted to the neck of the matrass, and reaching to the bottom of the vessel containing the Iodine and Water, transmit the gas through the mixture, until the Iodine entirely disappears. Filter the liquor, and immediately evaporate it, by a superior heat, to one-eighth part, and again filter it. Then gradually add as much Water of Carbonate of Potassa as will be sufficient to saturate the acid, which is known by the cessation of the effervescence. Then expose the mixture to heat, until the residual salt is dry and of a white colour. On this pour the Spirit, and digest by the aid of heat. Lastly, from the remaining salt, pour off the solution, evaporate it to dryness, and keep the residuum in a close vessel." *Dub.*

Since the appearance of the last edition of this work, the revisers of the U.S. Pharmacopœia have substituted the process of Baup and Caillot for that previously adopted for obtaining iodide of potassium. The French Codex and London Pharmacopœia had previously adopted this process; and the Edinburgh College, upon making this iodide officinal for the first time in the last edition of its Pharmacopœia, has selected it also. The first step of the process is to form the iodide of iron in solution, precisely as is done in the formula for that compound; and the second, to decompose it by carbonate of potassa, which gives rise to iodide of potassium in solution and a precipitate of carbonate of protoxide of iron. The solution of iodide of potassium is then separated by filtration from the precipitated carbonate, and evaporated so that crystals may form. As the precipitated carbonate, after the filtration, still retains a portion of the solution of iodide of potassium, it is washed, in order to dissolve this portion, and the resulting solution, after filtration, is added to that first obtained. The explanations above given, apply also to the *London* process. The London College takes the iron at one-third the weight of the iodine, instead of one-half as in the U.S. Pharmacopœia; and even this smaller quantity gives an excess of iron, but the larger proportion does no harm. The London process varies disadvantageously, in several particulars, from that of the U.S. Pharmacopœia. In the first place it is not easy to fix beforehand the quantity of carbonate of potassa necessary to decompose the iodide of iron, on account of the variable quality both of iodine and the alkaline carbonate. It is, therefore, better to add the alkaline solution only so long as it produces a precipitate; and, this rule being adopted, the quantity added in different operations, will be found sometimes more and sometimes less. The direction of the London College to strain immediately after the addition of the alkaline carbonate, gives rise to the inconvenience of obtaining a liquid, which becomes turbid

from a fresh formation of the ferruginous precipitate, and which requires a new filtration before it can be submitted to evaporation. This inconvenience is avoided by continuing the heat for half an hour after the addition of the alkaline solution, during which interval the salts fully react on each other and the precipitate is rendered less bulky, and more easily separable by the subsequent filtration. The London College have erred in using, in the different steps of their process, a quantity of water inconveniently large, which causes a waste of time and fuel in bringing the solution of the iodide of potassium to the necessary degree of concentration. The Edinburgh College, for no obvious reason, abandons the proportion of the iodine to the iron of 2 to 1, given in its formula for *Ferri Iodidi Syrupus*, and adopts the ratio of 2 to 1·2, thus using a still greater excess of metal. The carbonate of potassa is ordered in less proportion than in the U. S. and London formulæ, because it is directed to be dry. We have already expressed our preference of the plan of using a quantity of the alkaline carbonate, just adequate to complete the decomposition of the iodide of iron; but where a determinate quantity is used, it is desirable that it should be deficient rather than in excess; for if deficient, the only effect is to waste a portion of the iodide of iron, but if redundant, the excess contaminates the iodide of potassium obtained. The proportion of alkaline carbonate taken by the London and Edinburgh Colleges is not in excess, provided the iodine be dry; but if it contain considerable moisture, the carbonate ordered will be more than sufficient to decompose the iodide of iron formed. The solution of iodide of potassium, obtained by filtration, is directed by the Edinburgh College to be evaporated to dryness, in order to get rid of iron and other impurities, and the dry salt is purified by solution in water or alcohol, filtration, and crystallization. The evaporation to dryness, here directed, would be unnecessary, if the plan had been adopted of completing the reaction between the iodide of iron and alkaline carbonate, by the application of heat for a short time before filtration.

In the Dublin process, a stream of hydrosulphuric acid gas being passed through water in which iodine is diffused, the gas is decomposed, its sulphur is precipitated, and its hydrogen, by combining with the iodine, generates hydriodic acid, which remains in solution. The sulphur being separated by filtration, and the solution duly concentrated, the acid is converted into iodide of potassium by saturating it with carbonate of potassa, the carbonic acid of which, by being extricated, causes the effervescence. By evaporation to dryness, the iodide is obtained in the solid state. But lest it should be contaminated with some iodate and carbonate of potassa, the dry mass is directed to be digested with a portion of rectified spirit which takes up the iodide of potassium, and leaves these salts behind. The alcoholic solution is then evaporated to dryness, and the pure iodide obtained in the solid state. This process is not an eligible one; as it requires the formation of hydriodic acid, and the use of alcohol.

The simplest process for preparing iodide of potassium in quantity, and that preferred by many manufacturing chemists, is to add iodine to a hot solution of caustic potassa until the alkali is neutralized, when iodide of potassium and iodate of potassa will be generated, to evaporate to dryness, and to fuse the dry mass by a gentle red heat, in order to decompose the iodate. The fused mass is then dissolved in water, and the solution obtained crystallized. According to Mr. Scanlan the deoxidation of the iodate is easily effected by the intermixture of powdered charcoal with the two salts before they are subjected to heat. (*Pereira.*)

Properties, &c. Iodide of potassium is in white or transparent crystals,

permanent in a dry air, slightly deliquescent in a moist one, and having a sharp saline taste. It generally crystallizes in cubes. It is soluble in about two-thirds of its weight of cold water, and freely in rectified spirit; and when a hot saturated alcoholic solution is allowed to cool, it deposits the salt in crystals. Its solution imparts a blue colour to starch upon the addition of sulphuric acid, which acts by setting free iodine. Ether partially decomposes it, developing a yellow colour, and setting iodine free. (*Vogel*.) The aqueous solution is capable of taking up a large quantity of iodine, forming a liquid, containing the ioduretted iodide, of a deep brown colour. Exposed to heat it fuses, without losing weight, into a mass having a crystalline and pearly aspect, and at a red heat is volatilized without decomposition. The most usual impurities contained in this salt are the chlorides of potassium and sodium, and iodate and carbonate of potassa. The iodate and carbonate may be detected by their insolubility in alcohol. Iodide of potassium, containing iodate, becomes yellow by keeping, and evolves the odour of iodine. The iodate may be detected by adding a solution of tartaric acid to a solution of the suspected iodide. Bitartrate of potassa will be precipitated, and if the iodide be pure, a yellow colour is developed from the action of the air on the liberated hydriodic acid; but if any iodate be present, the test will set free both iodic and hydriodic acid, which, by their reaction, will instantly develop free iodine. (*Pereira*.) Carbonate of potassa is generally present in the proportion of from one to ten per cent., owing to faulty preparation; but sometimes it is fraudulently introduced. Dr. Christison has detected $74\frac{1}{2}$ per cent. of this impurity, and Dr. Pereira as high as 77 per cent. An adulteration by the carbonate under ten per cent. does not alter the crystalline appearance of the iodide, but gives it a greater tendency to deliquesce than the pure salt possesses; but when it is larger it renders the salt granular and highly deliquescent. This impurity may be detected by chloride of barium, which throws down a white precipitate of carbonate of baryta; by lime-water, which causes a milkiness (carbonate of lime); and by tincture of iodine, the colour of which is destroyed. The presence of a chloride may be determined by the use of nitrate of silver. This test will throw down nothing from the pure salt but iodide of silver, which is scarcely soluble in ammonia; while chloride of silver is readily soluble in it. If then a solution of the suspected iodide be precipitated by an excess of nitrate of silver, and agitated with ammonia, the latter will dissolve any chloride which may have been thrown down, and yield it again as a white precipitate on being saturated with nitric acid. If, on the other hand, the iodide of potassium be pure, the ammonia will only take up a minute quantity of iodide of silver, and the addition of the nitric acid will scarcely disturb the transparency of the solution. Iodide of potassium consists of one eq. of iodine 126.3, and one of potassium $39.15 = 165.45$. It contains no water of crystallization.

Medical Properties and Uses. This salt is diuretic and alterative. It is thought to have similar medical properties to those of iodine, which have been fully detailed under the head of *Iodinum*. It has a tendency to irritate the mucous membrane of the air-passages, as is shown by its sometimes occasioning cough, and an affection like cold in the head. When its use is long-continued, it occasionally excites ptyalism. Its obvious effects on the system are very variable, arising probably either from peculiarities of constitution, or from the unequal quality of the medicine itself. Thus in some cases it produces nausea, colic, and diarrhœa, in moderate doses; and in others is borne in large doses without inconvenience. Dr. Lugol considers it inferior to iodine as a therapeutic agent, and uses it, apparently,

for no other purpose than to promote the solubility of iodine in water. It has, however, been preferred by some practitioners for the purpose of producing the constitutional effects of iodine. Dr. De Renzy, of Carnew, used it with great success in hæmoptysis, and Dr. Graves of Dublin employed it with advantage in a very obstinate erythematic swelling of the hand. Dr. Williams, of London, considers it applicable to the treatment of various forms of secondary syphilis. He used it with success, in a majority of cases, in removing hard periosteal nodes, and found it beneficial in the treatment of tubercular forms of venereal eruptions. It is also considered as one of the best alterative remedies in mercurio-syphilitic sorethroat. Dr. Isaac Parrish, of this city, used it successfully in several cases of strumous inflammation of the eye, given in the compound syrup of sarsaparilla. It appeared to be particularly useful in promptly relieving the severe, neuralgic, circumorbital pain. (*Medical Examiner, N. S. i. 241.*) The dose is from two to ten grains or more, two or three times a day, given in solution. Some practitioners have reported the exhibition of enormous doses, such as two, four, and even six drachms daily, without inconvenience. Dr. Buchanan, of Glasgow, assures us that he has given the pure salt in doses of half an ounce, without any precaution being observed by the patient, except that of drinking freely of diluents. Notwithstanding this testimony, Dr. Lawrie, of the same city, reports several cases of dryness and irritation of the throat, ending in severe spasmodic croup, and one case of death following the sudden occurrence of dyspnœa, caused by the use of small doses of this iodide. (*Am. Journ. of the Med. Sciences, from the London Med. Gazette.*) There are certainly wanting new facts, to explain these discrepancies. Iodide of potassium passes quickly into the secretions, especially the urine. It may be detected in the latter by first adding to the cold secretion a portion of starch, and then a few drops of nitric acid, when a blue colour will be produced.

Iodide of potassium is employed as an external application in the form of ointment. (See *Unguentum Potassæ Hydriodatis.*) M. Breslau, of Munich, uses it externally in powder, mixed with eight parts of muriate of ammonia, and enclosed in a fine linen bag, which is applied to the part intended to be affected. The mixture soon becomes brown, in consequence of the commencement of decomposition, resulting in the formation of chloride of potassium, and the slow evolution of iodine.

POTASSII SULPHURETUM. *U. S.*, *Lond.*, *Ed.* POTASSÆ SULPHURETUM. *Dub.* Sulphuret of Potassium. Sulphuret of Potassa.

"Take of Sulphur *an ounce*; Carbonate of Potassa *two ounces*. Rub the Carbonate of Potassa, previously dried, with the Sulphur; melt the mixture in a covered crucible over the fire; then pour it out, and when it is cold put it into a bottle, which is to be well stopped." *U. S.*

"Take of Sulphur *an ounce*; Carbonate of Potassa *four ounces*. Rub them together, and place the mixture over the fire in a covered crucible, until they unite." *Lond.*

The Edinburgh and Dublin processes are essentially the same as that of the London College.

When carbonate of potassa is melted with half its weight of sulphur, as

in the U. S. process, the carbonic acid is expelled. Four eqs. of potassa and ten of sulphur may be supposed to react on each other. Three eqs. of potassa are decomposed into three eqs. of potassium and three of oxygen. The three eqs. of potassium unite with nine eqs. of sulphur to form three eqs. of tersulphuret of potassium. The three eqs. of oxygen, by uniting with the remaining eq. of sulphur, forms sulphuric acid, which combines with the undecomposed eq. of potassa to form sulphate of potassa. Thus the U. S. preparation may be considered to be a mixture of tersulphuret of potassium with sulphate of potassa; and the French Codex sulphuret, made from the same proportion of carbonate and sulphur, is stated in that work to have the same composition. It may be presumed that the product of the processes of the British Pharmacopœias has the same constituents, *plus* a certain portion of undecomposed carbonate of potassa, on account of the large excess of alkali taken. In performing the process, the mass, after it has become completely fused, should be poured out on a marble slab, and, as soon as it concretes, should be broken into pieces, and immediately transferred to a well-stopped bottle.

The different Pharmacopœias use the carbonate of potassa from pearlash; but this is considered by some as not sufficiently pure. In the process of M. Henry, which is stated to be the best that has yet been devised, the pure carbonate of potassa is employed. His formula is as follows: Mix two parts of real salt of tartar with one of roll sulphur reduced to powder, and put the mixture into flat-bottomed matrasses, which should be only two-thirds filled by it. These are placed on a sand-bath, at equal distances, and the fire is applied, so as, at first, to produce only a gentle heat, which is afterwards increased. Care must be taken that the necks of the matrasses do not become obstructed. The heat is continued until the matter is brought to the state of tranquil fusion, when it is allowed to cool. The mass obtained, which is compact, smooth, and of a fine yellow colour, is broken into pieces and preserved in well-stopped bottles.

Properties, &c. Sulphuret of potassium, when properly prepared, is a hard brittle substance, having a nauseous, alkaline, and bitter taste. Its colour is liver-brown, and hence its former name of *hepar sulphuris* or *liver of sulphur*. The colour of the surface of a fresh fracture is brownish-yellow. It is inodorous when dry, but emits a slightly fetid smell when moist, owing to the extrication of a small portion of sulphuretted hydrogen gas. It is completely soluble in water, forming a liquid of an orange-yellow colour, and exhaling the smell of sulphuretted hydrogen. By exposure to the air it attracts oxygen, and the sulphuret of potassium is gradually converted into sulphate of potassa, when the preparation becomes inodorous, and white on the surface. The solution is decomposed by the mineral acids, which extricate sulphuretted hydrogen, and precipitate the excess of sulphur in the state of hydrate. It is also incompatible with solutions of most of the metals, which are precipitated as sulphurets. B.

Medical Properties and Uses. Sulphuret of potassium is a local irritant, and, in small frequently repeated doses, is said to increase the frequency of the pulse, the heat of skin, and the different secretions, especially those of the mucous membranes. Occasionally it vomits and purges. It acts, moreover, as an antacid, and produces the general effects of sulphur upon the system. By some it is maintained to be sedative, and directly to reduce the action of the heart. This effect it probably produces, when taken in considerable quantities, by the development of sulphuretted hydrogen. In over doses, it acts, according to Orfila, as a violent poison, corroding the

stomach, and depressing the powers of the nervous system. The complaints in which it has been most advantageously employed are chronic rheumatism and gout, and various cutaneous affections. It has been given with less benefit in painter's colic, asthma, and chronic catarrh, and acquired a short-lived reputation as a remedy in croup, after the publication of the essay to which the prize offered by Napoleon for the best dissertation on that disease was awarded. It is said, in some cases of cancer, to have assisted the palliative operation of hemlock. In consequence of its property of forming insoluble sulphurets when mixed with the metallic salts, it has been proposed as an antidote for some of the mineral poisons, such as corrosive sublimate, arsenious acid, the salts of copper, and the preparations of lead. Orfila, however, has proved that it does not prevent the effects of these poisons, but on the contrary is itself highly poisonous when given in large doses. Dissolved in water it has proved very efficacious as an external application in cutaneous diseases, and in scabies is an almost certain remedy. It may be used for this purpose in the form of lotion, bath, or ointment. For a lotion it may be dissolved in water in the proportion of from fifteen to thirty grains to the fluidounce, and for a bath, the same quantity or rather more may be added to a gallon of water. A very small proportion of muriatic or sulphuric acid may in either case be added to the solution. The ointment is made by mixing half a drachm of the sulphuret with an ounce of lard.

The dose of the sulphuret of potassa is from two to ten grains, repeated several times a day, and given in pill with liquorice, or in solution with syrup. In infantile cases of croup, from one to four grains were given every three or four hours. W.

POTASSÆ SULPHURETI AQUA. *Dub. Water of Sulphuret of Potassa.*

“Take of Washed Sulphur *one part*; Water of Caustic Potassa *eleven parts*. Boil for ten minutes, and filter through paper. Keep the liquor in well stopped bottles. The specific gravity of this solution is 1.117.” *Dub.*

When sulphur is boiled with a solution of caustic potassa, sulphuret of potassium and hyposulphite of potassa are formed in solution. Accordingly, this preparation is not a solution of sulphuret of potassa, as it is called by the Dublin College; neither is it identical with an aqueous solution of the preceding preparation.

Properties, &c. This liquid has an unctuous feel and a deep orange colour. It is decomposed by acids, which cause an effervescence of hydrosulphuric acid, and a milky appearance from the precipitation of sulphur. Upon exposure to the air it is gradually converted into a solution of the sulphate of potassa. It is similar in medical properties to the last preparation, and is used internally and externally for the most part in cutaneous eruptions. The dose is from ten minims to a fluidrachm, diluted with water, and given two or three times a day. When used as a bath it imparts an orange colour to the skin. B.

PULPÆ.

Pulps.

The following general directions are given in the Pharmacopœias in relation to the extraction of pulps:

“Fruits of which the pulps are to be extracted, if unripe, or ripe and dry,

are to be boiled in a little water until they become soft. Then the pulps, expressed through a hair sieve, are to be slowly evaporated to a proper consistence." *Dub.*

"Set *pulpy fruits*, if unripe, or ripe and dry, in a moist place to soften; then express the pulps through a hair sieve; afterwards boil them with a gentle fire, frequently stirring; lastly, evaporate the water by means of a water-bath, until the pulps become of a proper consistence. Of fruits which are ripe and fresh, express the pulp or juice through a sieve, without boiling." *Lond.*

There are very few fruits the pulps of which are now employed in pharmacy. For these few the directions of the Dublin College are preferable to those of the London, which are indeed impracticable; as dried fruits often do not become sufficiently moist, by mere exposure in a damp place, to admit of the subsequent treatment ordered, and besides, would almost always become mouldy. *W.*

CASSIÆ FISTULÆ PULPA. *U.S.* CASSIA. *Lond.* CASSIÆ PULPA. *Ed.* CASSIA FISTULA. *Dub.* *Pulp of Purging Cassia.*

"Take of Purging Cassia, bruised, *a convenient quantity*. Pour boiling water on the bruised pods so that the pulp may be softened; then strain, first through a coarse sieve, and afterwards through a hair one, and evaporate by means of a water-bath to the proper consistence." *U.S.*

"Pour boiling Water upon bruised Cassia Pods, so that the pulp may be washed out, and press this first through a coarse sieve, and afterwards through a hair sieve; then evaporate by means of a water-bath until the pulp acquires a proper consistence." *Lond.*

Cassia pulp has a blackish colour, a slight rather sickly odour, and a sweet mucilaginous taste. It is apt to become sour by exposure. For its composition and effects, see *Cassia Fistula*.

Off. Prep. Confectio Cassiæ, *Lond.*; Confectio Sennæ, *U.S., Lond.*

PRUNI PULPA. *U.S.* *Pulp of Prunes.*

"Take of Prunes *a convenient quantity*. Soften the Prunes in the vapour of boiling water, and having separated the stones, beat the remainder in a marble mortar, and press it through a hair sieve." *U.S.*

The prunes may be softened, as above directed, by placing them on a perforated plate or diaphragm, or a wire sieve, or suspending them in a net, over boiling water.

Off. Prep. Confectio Sennæ, *U.S.* *W.*

TAMARINDI PULPA. *U.S.* TAMARINDUS. *Lond., Ed.* TAMARINDUS INDICA. *Dub.* *Pulp of Tamarinds.*

"Take of Tamarinds *a convenient quantity*. Digest them with a small quantity of water until they become of a uniform consistence; then separate the seeds and filaments by pressing through a hair sieve." *U.S.*

They should be digested in an unglazed earthenware vessel over hot ashes, or by means of a sand-bath.

W.

PULVERES.

Powders.

The form of powder is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure. As the effect of pulverization is to expose a more extended surface to the action of the air, care should be taken to keep substances which are liable to be injured by such exposure, in closely stopped bottles. In many instances it is also important to exclude the light, which exercises a very deleterious influence over numerous medicinal agents when minutely divided. In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities as they are wanted for use.

Powders may be divided into the *simple*, consisting of a single substance, and the *compound*, of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then united. An exception, however, to this rule, is the employment of one substance to facilitate by its greater hardness the minute division of another, as in the *powder of ipecacuanha and opium*. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders; the former, because by absorbing moisture, they render the preparation damp and liable to spoil, the latter, because they are apt to become rancid, and impart an unpleasant odour and taste to the mixture.

The lighter powders may in general be administered suspended in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or some of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar.

The *Dublin College* gives the following general directions for the preparation of powders: "The substances to be powdered, having been previously dried, are to be beaten in an iron mortar. The powder is then to be separated, by sifting it through a hair sieve, and is to be kept in close vessels." These directions, however, are not sufficiently explicit. It is not proper to beat the substance in the mortar till it is completely pulverized; as the portion already powdered interferes with the action of the pestle upon that remaining unpowdered, while the finer matter is apt to be dissipated; so that there is a loss both of time and material. The proper plan is to sift off the fine powder after a short trituration, then to return the coarser parts to the mortar, and to repeat several times this alternate pulverization and sifting, until the whole is brought to the proper degree of fineness.

W.

PULVIS ALOËS COMPOSITUS. *Lond., Dub. Compound Powder of Aloes.*

"Take of Aloes *an ounce and a half*; Guaiacum Resin *an ounce*; Compound Powder of Cinnamon *half an ounce*. Rub the Aloes and the Guaiacum Resin, separately, into powder; then mix them with the Compound Powder of Cinnamon." *Lond.*

The *Dublin College* gives the same directions, particularizing the hepatic

aloes, and substituting their own aromatic powder for the compound powder of cinnamon of the London College.

The tendency of pulverized guaiac to concrete, and the excessively bitter taste of aloes, which is but imperfectly concealed by the aromatic addition, render the form of powder ineligible for the exhibition of these medicines. The preparation is a warm stimulant cathartic, but is little used. The dose is from fifteen to thirty grains. W.

PULVIS ALOËS ET CANELLÆ. U.S. **PULVIS ALOËS CUM CANELLÂ. Dub.** *Powder of Aloes and Canella. Hiera Picra.*

"Take of Aloes [hepatic, *Dub.*] a pound; Canella three ounces. Rub them separately into very fine powder, [into powder, *Dub.*] and mix them." *U. S., Dub.*

This preparation has long been known under the name of *hiera picra*. The canella serves to correct the griping property, and imperfectly to cover the taste of the aloes; but the unpleasant bitterness of the latter is still very obvious in the mixture, which would be better given in the form of pill than of powder. It is a popular remedy in amenorrhœa, and may be used for all the purposes to which aloes is applied. It is sometimes administered, in domestic practice, infused in wine or spirit. The dose is from ten to twenty grains. W.

PULVIS ALUMINIS COMPOSITUS. Ed. *Compound Powder of Alum.*

"Take of Alum four ounces; Kino one ounce. Mix them and reduce them to fine powder." *Ed.*

A solution of alum is decomposed by a solution of kino, and it is probable that the same effect takes place when the two substances, mixed in the state of powder, are introduced into the stomach; but whether their astringency is materially affected by the change is uncertain. The preparation may be employed in diarrhœa, menorrhagia, and hemorrhage from the stomach or bowels, and externally to suppress hemorrhage, or as an astringent application to flabby ulcers. The dose is from five to twenty grains. W.

PULVIS AROMATICUS. U.S., Ed., Dub. **PULVIS CINNAMOMI COMPOSITUS. Lond.** *Aromatic Powder.*

"Take of Cinnamon, Ginger, each, two ounces; Cardamom deprived of the capsules, Nutmeg, grated, each, an ounce. Rub them together into a very fine powder." *U. S.*

The London College directs two ounces of cinnamon, an ounce and a half of cardamom, an ounce of ginger, and half an ounce of long pepper; the Edinburgh, equal parts of cinnamon, cardamom, and ginger; the Dublin, two ounces of cinnamon, an ounce of cardamom seeds freed from their capsules, an ounce of ginger, and a drachm of long pepper.

The cardamom seeds should always be separated from their capsules before pulverization; and the powder, when prepared, should be kept in well stopped bottles. The London and Dublin preparations are more pungent than those of the U. S. and Edinburgh Pharmacopœias, in consequence of the long pepper which they contain. These powders are stimulant and carminative, and may be given in the dose of from ten to thirty grains, in cases of enfeebled digestion accompanied with flatulence; but they are chiefly used as corrigents and adjuvants of other medicines.

Off. Prep. Confectio Aromatica, *U. S., Ed.*; Confectio Opii, *U. S., Ed.*; Pilulæ Aloës et Ferri, *Ed.*; Pilulæ Cambogiæ, *Ed.*; Pulvis Aloës Comp., *Lond., Dub.* W.

PULVIS ASARI COMPOSITUS. *Dub.* *Compound Powder of Asarabacca.*

“Take of dried Leaves of Asarabacca *an ounce*; dried Lavender Flowers *a drachm.* Rub them together to powder.” *Dub.*

This is an agreeable and efficacious errhine, useful in some cases of obstinate headache, toothache, and chronic ophthalmia. Five or six grains, snuffed up the nostrils at bedtime, excite sneezing and a copious discharge of mucus, which continues to flow on the following day. W.

PULVIS CRETÆ COMPOSITUS. *Lond., Ed., Dub.* *Compound Powder of Chalk.*

“Take of Prepared Chalk *half a pound*; Cinnamon *four ounces*; Tormentil, Gum Arabic, each, *three ounces*; Long Pepper *half an ounce.* Rub them separately into very fine powder, and then mix them.” *Lond., Dub.*

“Take of Prepared Chalk *four ounces*; Cinnamon, in fine powder, *one drachm and a half*; Nutmeg, in fine powder, *a drachm.* Triturate them well together.” *Ed.*

In the Edinburgh preparation, the aromatics are in too small a quantity to serve any other purpose than to communicate an agreeable flavour to the chalk, which is the only active ingredient. The powder of the London and Dublin Colleges is, on the contrary, warm, stimulant, and astringent, as well as antacid; and is well calculated for the treatment of diarrhœa, connected with acidity and unattended with inflammatory symptoms. In such a combination, however, the proper proportion, and even the choice of the ingredients, varies so much with the symptoms of the case, that they might with propriety be left to extemporaneous prescription. The dose of the compound powder of chalk is from ten to twenty grains, given in mucilage or sweetened water, and frequently repeated.

Off. Prep. Pulvis Cretæ Comp. cum Opio, *Lond., Ed., Dub.* W.

PULVIS CRETÆ COMPOSITUS CUM OPIO. *Lond., Dub.*
PULVIS CRETÆ OPIATUS. *Ed.* *Compound Powder of Chalk with Opium.*

“Take of Compound Powder of Chalk *six ounces and a half*; Hard Opium, in powder, *four scruples.* Mix them.” *Lond., Dub.*

“Take of Compound Chalk Powder *six ounces*; Powder of Opium *four scruples.* Triturate them together thoroughly.” *Ed.*

The addition of the opium greatly increases the efficacy of the compound powder of chalk in diarrhœa; and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Two scruples of the London or Dublin powder, and thirty-seven grains of the Edinburgh, contain a grain of opium. In the diarrhœa of adults from ten to twenty grains may be given for a dose, and repeated several times a day, or after each evacuation. W.

PULVERES EFFERVESCENTES. *Ed.* *Effervescing Powders.*

“Take of Tartaric Acid *one ounce*; Bicarbonate of Soda *one ounce and 54 grains*, or Bicarbonate of Potassa *one ounce and 160 grains.* Reduce the Acid and either Bicarbonate separately to fine powder, and divide each into sixteen powders. Preserve the acid and alkaline powders in separate papers of different colours.” *Ed.*

This is a formula, introduced into the last edition of the Edinburgh Pharmacopœia, for a preparation which has been long in use under the name of

Soda powders. The common soda powders contain the ingredients in somewhat different proportions; consisting of twenty-five grains of the acid in one paper, and thirty of the bicarbonate in the other. Besides, they are always prepared with the bicarbonate of soda; while the Edinburgh Pharmacopœia allows a choice between that and the bicarbonate of potassa. This want of precision is highly objectionable in officinal formulæ. If it was thought advisable that the practitioner should have the opportunity of prescribing either of these preparations at his option, they should have had different names.

The powders are administered in solution. An acid and an alkaline powder may be dissolved in separate portions of water and then mixed; or they may be thrown together, or successively, into the same portion of water. The whole draught should be half a pint or somewhat less. It may be rendered more agreeable by adding two or three fluidrachms of syrup of ginger or orange peel to the water before dissolving the powders. The rationale is simple. The tartaric acid seizes the alkali of the bicarbonate, forming a tartrate of soda or of potassa as the case may be, while the carbonic acid escapes with effervescence. The effervescing powders are refrigerant and very slightly laxative; and afford an agreeable and refreshing drink, suitable to febrile complaints. W.

PULVIS IPECACUANHÆ ET OPII. U.S. PULVIS IPECACUANHÆ COMPOSITUS. *Lond., Ed., Dub. Powder of Ipecacuanha and Opium. Dover's Powder.*

“Take of Ipecacuanha, in powder, Opium, in powder, each, *a drachm*; Sulphate of Potassa *an ounce*. Rub them together into a very fine powder.” U. S.

All the British Colleges employ the same ingredients as above, and in the same proportions. The *London College* having ordered them in the state of powder, simply directs them to be mixed together. The *Edinburgh College* orders eight times the amount of the materials, and directs them to be triturated thoroughly together. The *Dublin College* first rubs the opium and sulphate of potassa together into powder, and then mixes the pulverized ipecacuanha with them.

The sulphate of potassa in this preparation serves, by the hardness of its particles, to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha, upon which the peculiar virtues of the compound depend. It also serves to dilute the active ingredients, and thus allow of their division into minute doses adapted to the complaints of children. This composition, though usually called *Dover's powder*, does not precisely correspond with that originally recommended by Dr. Dover, which was prepared as follows. Four ounces of nitrate of potassa and the same quantity of sulphate of potassa, were mixed together in a red-hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, was then added, and ground to powder with the saline mixture; lastly, an ounce of ipecacuanha and an ounce of liquorice root, in powder, were mixed with the other ingredients. This process was adopted in the former French Codex, and has been retained with very slight change in the present.

The powder of ipecacuanha and opium is an admirable anodyne diaphoretic, not surpassed, perhaps, by any other combination in its power of promoting the cutaneous secretion. Opium itself has a strong tendency to the skin, evinced both by the occasional diaphoresis and by the itching and tingling sensation which it excites. While the vessels of the skin are

stimulated by this ingredient of the powder, the secreting orifices are relaxed by the ipecacuanha, and the combined effect is much greater than that which results from either separately. At the same time the general stimulating influence of the opium, and its tendency to operate injuriously on the brain, are counteracted; so that the mixture may be given with safety in cases which might not admit of the use of opium alone. The preparation is applicable to all cases, not attended with much fever, or cerebral disease, or sick stomach, in which there is an indication for profuse diaphoresis, especially in painful affections, or those connected with unhealthy discharges. It is admirably adapted to the treatment of the phlegmasiæ, particularly rheumatism and pneumonia, when complicated with a typhoid tendency, or after a sufficient reduction of arterial excitement by the lancet or other mode of depletion. Under similar circumstances it is useful in dysentery, diarrhœa, and the various hemorrhages, especially that from the uterus. It is sometimes also given in dropsy. In bowel affections, and whenever the hepatic secretion is deranged, it is frequently combined with small doses of calomel.

Ten grains of the powder contain one grain of opium. The dose is from five to fifteen grains, given diffused in water, or mixed with syrup, or in the form of bolus, and repeated at intervals of four, six, or eight hours, when it is desirable to maintain a continued diaphoresis. Its action may be materially promoted by warm drinks, such as lemonade, or balm tea, which, however, should not be given immediately after the powder, as they might provoke vomiting.

Off. Prep. Pilulæ Ipecacuanhæ Compositæ, *Lond.*; Pilulæ Ipecacuanhæ et Opii, *Ed.* W.

PULVIS JALAPÆ COMPOSITUS. *U. S., Lond., Ed., Dub.*
Compound Powder of Jalap.

“Take of Jalap, in powder, *an ounce*; Bitartrate of Potassa, in powder, *two ounces*. Mix them.” *U. S.*

The *London College* takes *three ounces* of jalap, *six ounces* of bitartrate of potassa, and *two drachms* of ginger. The *Edinburgh* and *Dublin Colleges* take the same ingredients in the same proportion as the *U. S. Pharmacopœia*, and direct them to be rubbed together to a very fine powder.

The bitartrate, by being rubbed with the jalap, is thought to favour its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of tartar (see *Jalapa*), is much used in this country as a cathartic in dropsy and serofulous affections of the joints and glands. The dose of the official powder is from thirty grains to a drachm. W.

PULVIS KINO COMPOSITUS. *Lond., Dub.* *Compound Powder of Kino.*

“Take of Kino *fifteen drachms*; Cinnamon *half an ounce*; hard Opium *a drachm*. Rub them separately to a very fine powder, and then mix them.” *Lond., Dub.*

This is an anodyne astringent powder, useful in some forms of diarrhœa, but of which the composition would be better left to extemporaneous prescription, as the proportion of the ingredients should vary with the circumstances of the case. Twenty grains contain one grain of opium. The dose is from five grains to a scruple. W.

PULVIS PRO CATAPLASMATE. *Dub. Powder for a Cataplasm.*

"Take of Flaxseed which remains after the expression of the oil *one part*; Oatmeal *two parts*. Mix them." *Dub.*

This is a good material for the formation of poultices, but hardly deserves a place among the officinal preparations. The unpressed flaxseed meal is preferable to that which has been pressed, as the oil which it contains causes it to retain longer a soft consistence. W.

PULVIS RHEI COMPOSITUS. *Ed. Compound Powder of Rhubarb.*

"Take of Magnesia *one pound*; Ginger, in fine powder, *two ounces*; Rhubarb, in fine powder, *four ounces*. Mix them thoroughly, and preserve the powder in well-closed bottles." *Ed.*

This is a very good antacid laxative combination, well adapted to bowel complaints, especially in children. The dose for an adult is from half a drachm to a drachm, for a child two or three years old, from five to ten grains. W.

PULVIS SALINUS COMPOSITUS. *Ed., Dub. Compound Saline Powder.*

"Take of Pure Muriate of Soda, Sulphate of Magnesia, each, *four ounces*; Sulphate of Potassa *three ounces*. Dry the salts separately with a gentle heat, and pulverize each, then triturate them well together, and preserve the mixture in well-closed vessels." *Ed.*

The *Dublin* process is essentially the same as the above.

This is an aperient powder, and may be given with advantage in costive habits, in the dose of two or three drachms, dissolved in half a pint of water or carbonic acid water, before breakfast. W.

PULVIS SCAMMONII COMPOSITUS. *Lond., Ed., Dub. Compound Powder of Scammony.*

"Take of Scammony, hard Extract of Jalap, each, *two ounces*; Ginger *half an ounce*. Rub them separately to a very fine powder; and then mix them." *Lond., Dub.*

"Take of Scammony, and Bitartrate of Potash, *equal parts*. Triturate them together to a very fine powder." *Ed.*

It should be observed, that the compound of the Edinburgh College is essentially different from that of the London and Dublin Colleges; but we do not think that either of them is an eligible preparation. The cream of tartar in the former can serve little other purpose than to assist in the pulverization of the scammony, which does not require any peculiar care in this respect. In the latter, though the ginger may tend to correct the griping property of the purgative ingredients, the extract of jalap too closely resembles the scammony in its mode of operation to exert any important modifying influence upon it. The dose of the London powder is from ten to twenty grains, of that directed by the Edinburgh Pharmacopœia, from fifteen to thirty grains. W.

PULVIS TRAGACANTHÆ COMPOSITUS. *Lond., Ed. Compound Powder of Tragacanth.*

"Take of Tragacanth, in powder, Gum Arabic, in powder, Starch, each, *an ounce and a half*; Sugar [refined] *three ounces*. Rub the Starch and Sugar together to powder, then add the Tragacanth and Gum Arabic, and mix them all." *Lond.*

The *Edinburgh* process corresponds with the above.

This is applicable to the general purposes of the demulcents; but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders. The dose is from thirty grains to a drachm, mixed with water or other mild liquid.

QUINIA.

Preparations of Quinia.

QUINIÆ SULPHAS. *U. S.* QUINÆ DISULPHAS. *Lond.* QUINÆ SULPHAS. *Ed.* QUININÆ SULPHAS. *Dub.* *Sulphate of Quinia.*

“Take of Yellow Bark, in coarse powder, *four pounds*; Muriatic Acid *three fluidounces*; Lime, in powder, *five ounces*; Water *five gallons*; Sulphuric Acid, Alcohol, Animal Charcoal, each, *a sufficient quantity*. Boil the Bark in one-third of the Water mixed with one-third of the Muriatic Acid, and strain through linen. Boil the residue twice successively with the same quantity of Water and Acid as before, and strain. Mix the decoctions, and, while the liquor is hot, gradually add the Lime, previously mixed with two pints of water, stirring constantly, until the quinia is completely precipitated. Wash the precipitate with distilled water, and, having pressed and dried it, digest it in boiling Alcohol. Pour off the liquor and repeat the digestion several times, until the Alcohol is no longer rendered bitter. Mix the liquors, and distil off the Alcohol, until a brown viscid mass remains. Upon this substance, removed from the vessel, pour about half a gallon of Distilled Water, and, having heated the mixture to the boiling point, add as much Sulphuric Acid as may be necessary to dissolve the impure alkali. Then add an ounce and a half of Animal Charcoal, boil for two minutes, filter the liquor while hot, and set it aside to crystallize. Should the liquor, before filtration, be entirely neutral, acidulate it very slightly with Sulphuric Acid; should it, on the contrary, change the colour of litmus paper to a bright red, add more Animal Charcoal. Separate the crystals from the liquor, dissolve them in boiling water slightly acidulated with Sulphuric Acid, add a little Animal Charcoal, filter, and set aside to crystallize. Wrap the crystals in bibulous paper, and dry them with a gentle heat. The mother-waters may be made to yield an additional quantity of Sulphate of Quinia by precipitating the Quinia with Solution of Ammonia, and treating the precipitated alkali with Water, Sulphuric Acid, and Animal Charcoal, as before.” *U. S.*

The *London College* exhausts yellow bark by water acidulated with sulphuric acid, throws down the acid by hydrated oxide of lead, washes the precipitate with distilled water, boils down the liquors to a fourth part, filters, adds water of ammonia in order to decompose the kinate of quinia, washes the precipitated quinia till the water ceases to be rendered alkaline, saturates the residue with diluted sulphuric acid, digests with animal charcoal, filters, and finally, having thoroughly washed the charcoal, cautiously evaporates the liquor so that it may crystallize. This process, however, has not been found to answer well in practice. It may not be irrelevant to mention here that the *London College*, though it thus gives a process for the preparation of sulphate of quinia, places the alkali itself, under the name of QUINIA, in its Catalogue of the *Materia Medica*.

“Take of Yellow Bark, in coarse powder, *one pound*; Carbonate of Soda *eight ounces*; Sulphuric Acid *half a fluidounce*; Purified Animal Charcoal *two drachms*. Boil the bark for an hour in four pints [Imperial measure] of water, in which half the carbonate of soda has been dissolved; strain and ex-

press strongly through linen or calico; moisten the residuum with water and express again; and repeat this twice. Boil the residuum for half an hour with four pints of water and half the Sulphuric Acid; strain, express strongly, moisten with water, and express again. Boil the residuum with three pints of water and a fourth part of the Acid; strain and squeeze as before. Boil again the residuum with the same quantity of water and Acid, strain and squeeze as formerly. Concentrate the whole acid liquids to about a pint; let the product cool; filter it, and dissolve in it the remainder of the Carbonate of Soda. Collect the impure quina on a cloth, wash it slightly, and squeeze out the liquor with the hand. Break down the moist precipitate in a pint of distilled water, add one fluidscruple of Sulphuric Acid, heat it to 212° , and stir occasionally. Should any precipitate retain its gray colour, and the liquid be neutral, add Sulphuric Acid drop by drop, stirring constantly, till the gray colour disappears. Should the liquid redden litmus, neutralize it with a little carbonate of soda. Should crystals form on the surface, add boiling distilled water to dissolve them. Filter through paper, preserving the funnel hot; set the liquid aside to crystallize; collect and squeeze the crystals; dissolve them in a pint of distilled water heated to 212° ; digest the solution for fifteen minutes with the Animal Charcoal; filter, and crystallize as before. Dry the crystals with a heat not exceeding 140° . The mother liquors of each crystallization will yield a little more salt by concentration and cooling." *Ed.*

It should be observed, that the Imperial measure is employed in the above process.

The *Dublin College* exhausts the bark by digestion with water acidulated with sulphuric acid, adds to the liquor sufficient lime to saturate the acid, dries the precipitate on blotting paper, digests it with rectified spirit, filters, distils the spirituous liquor to dryness, adds diluted sulphuric acid to the residuum in slight excess, and finally crystallizes by concentration and cooling.

The present U. S. process, which is essentially that of the French Codex, differs from the one given in the Pharmacopœia of 1830, in the use of muriatic instead of sulphuric acid for acidulating the water first employed, and in the greater minuteness of the details. Both this and the French Codex process, as well as that of the Dublin College, are modifications of the plan originally proposed by M. Henry, Jun., of Paris, for which he received a prize from the French Academy of Sciences, and which has been almost universally employed where alcohol is not too expensive. Henry's process, with all its details, may be found in previous editions of this work; but, as its repetition is rendered unnecessary by the greater precision of the official formula, we omit it in the present edition. An explanation of the several directions given in the U. S. Pharmacopœia will be useful to the student by enabling him to comprehend each step of the process.

The yellow bark (Calisaya, or royal yellow) is the variety selected, because this contains quinia in the largest proportion, and most free from admixture with cinchonia. The alkali exists in the bark combined with kinic acid, and probably also, with one or more of the colouring principles, as suggested by M. Henry. As in this latter state it is of difficult solubility, if it be not insoluble in water, the whole of the quinia cannot be extracted from the bark by means of that liquid alone. Berzelius, however, attributes the difficulty of exhausting the bark to the circumstance, that water converts the native neutral kinates into soluble superkinates which are dissolved, and insoluble subkinates which remain. By adding muriatic or sulphuric acid to the water in such quantities as to be in excess in relation

to the quinia, the whole of the alkali combines with the acid to form a very soluble muriate or sulphate, in which state it exists, together with various impurities, in the decoctions procured by the first steps of the process. By the addition of lime to the filtered and mixed decoctions, the salt of quinia is decomposed, giving up its acid to the lime, while the quinia is liberated, and being insoluble in water, is precipitated—the water retaining most of the impurities. If sulphuric acid was employed in the commencement of the process, sulphate of lime is deposited along with the quinia; but if muriatic acid was employed, the resulting chloride of calcium is retained in solution; and a reason is thus afforded for the preference of the latter acid. But, in either case, the excess of lime, and a compound formed of the lime and colouring matter, which is insoluble both in water and alcohol, are thrown down with the alkali. The precipitate having been washed in order to purify it from every thing soluble in water, the next step is to separate the quinia from the insoluble impurities. This is accomplished by the agency of alcohol, which dissolves the former, and leaves most of the latter behind. The whole of the alkali having been abstracted, the alcoholic solution of quinia is then concentrated so as to afford a brown viscid mass, which is impure quinia. Portions of this may be reserved, if thought advisable, for the preparation of other salts of quinia. The mass is treated with boiling distilled water acidulated with sulphuric acid, which forms a disulphate (the officinal sulphate) with the quinia, and, being somewhat in excess, enables the salt to be readily dissolved. The animal charcoal now added should be the *unpurified* bone-black, the carbonate of lime contained in which neutralizes a portion of the sulphuric acid, and thus facilitates the crystallization of the sulphate of quinia when the solution cools. Should the quantity of the bone-black added be sufficient to render the solution quite neutral, so as in no degree to affect litmus paper, as much sulphuric acid should be added as will give the paper a slightly vinous tint; for otherwise the crystallization may commence before the liquor is completely filtered. If, on the contrary, the bone-black has been deficient, and the solution colours litmus paper cherry-red, more of that substance is to be added. This, however, is merely an incidental advantage of the animal charcoal; its chief use being to decolorize the liquid. The second crystallization is necessary to obtain the salt of quinia free from colour; and sometimes, it cannot be rendered perfectly white without a third. It is essential that the heat employed in drying the crystals should be gentle, in order to prevent their efflorescence. The small quantity of cinchonia contained in Calisaya bark is extracted in this process along with the quinia, but, as the sulphate of the former alkali is more soluble than that of the latter, it remains in the mother liquors.

The Edinburgh process was contrived so as to avoid the use of alcohol, which is so costly in Great Britain as materially to affect the economy of the operation. The object of the first boiling with water and carbonate of soda, is to get rid of the colouring principles, resin, and kinic acid, while the quinia is left behind. The residuum is next exhausted by means of water acidulated with sulphuric acid, which affords an impure solution of sulphate of quinia. This, after being sufficiently concentrated, is decomposed by carbonate of soda, which seizes the acid and precipitates the quinia with some colouring matter. The remaining steps of the operation are similar to those of the U. S. process, except that animal charcoal is employed only previous to the last crystallization; and the advantage incidentally obtained from it, of neutralizing the acid when in excess, is gained in the Edinburgh process by the use of carbonate of soda. Both Pereira

and Christison speak favourably of this process; but it is scarcely probable that it will supersede the former where alcohol can be had cheaply.

According to the French Codex, one thousand parts of yellow bark ought to yield from 29 to 30 parts of sulphate of quinia, when treated by the process first described. But this amount is not often reached. We have been informed by Mr. John Farr, of Philadelphia, who is largely concerned in the manufacture of sulphate of quinia, that the Calisaya bark employed by him yields an average product of about two per cent. of the salt; and a manufacturer in London told Dr. Christison that the extremes which he obtained from different specimens of bark were one and a half and three per cent.

Sulphate of quinia may be obtained from any of the varieties of Peruvian bark by the above processes; but should any other than the Calisaya bark be employed, a large proportion of sulphate of cinchonia will necessarily result from the operation, and, being much more soluble than the sulphate of quinia, will remain dissolved in the residuary liquor from which the latter will have crystallized. To obtain the *cinchonia* separate, the following method, originally suggested by Pelletier and Caventou, may be employed. Magnesia, lime, or a solution of potassa as employed by M. Callaud, is added to the mother waters in excess. The cinchonia is precipitated together with a portion of quinia which has remained in the solution, and with the excess of magnesia or lime if one of these earths has been employed. The precipitate is collected on a filter, washed with hot water, then dried, and treated with boiling alcohol, which dissolves the vegetable alkalies. The alcoholic solution is filtered while hot, and the residue afterwards treated in the same manner with successive portions of alcohol, till it is quite exhausted. The solutions having been mixed together, are now concentrated by the distillation of the alcohol, and allowed to cool, when they deposit cinchonia in the crystalline state. Successive evaporations and refrigerations afford new crops of crystals, and the process should be continued till no more can be obtained. The cinchonia thus procured, if impure, should be reconverted into a sulphate and treated as before, animal charcoal being employed to free it from colour. The quinia which remains in the mother waters, as it will not crystallize, may be obtained by evaporation to dryness, or may be converted into the crystallizable sulphate by the addition of sulphuric acid. To obtain the *sulphate of cinchonia*, mix the alkali with a small quantity of water, heat the mixture, and add gradually dilute sulphuric acid sufficient to saturate it; then boil with animal charcoal previously washed with muriatic acid, and filter the liquor while hot. Upon cooling it will deposit crystals of the sulphate, and, by repeated evaporation and crystallization, will yield all the salt which it holds in solution.

Properties. Sulphate of quinia is in fine, silky, slightly flexible, needle-shaped crystals, interlaced among each other, or grouped in small star-like tufts. Its taste is intensely bitter, resembling that of the yellow bark. It effloresces slightly on exposure to the air, and, at a moderate heat, loses its crystalline form in consequence of the escape of its water of crystallization. At a temperature of 212° it becomes luminous, especially when rubbed. At about 240° it melts, assuming the appearance of wax. It is very slightly soluble in cold water, requiring, according to M. Baup, 740 parts at 54° F. for solution, while at the boiling point it is dissolved in 30 parts of water, which deposits it upon cooling. Its cold solution is opalescent. It is soluble in about 60 parts of cold alcohol of 0.835, but only to a very small extent in ether. The diluted acids, even tartaric and oxalic acids in excess, dissolve it with great facility. With an additional equivalent of sulphuric

acid it forms another sulphate, which is much more soluble in water than the officinal salt, and crystallizes from its solution with much greater difficulty. It was at first supposed that, of these two sulphates, the officinal salt consisted of one equivalent of each of its components, while the other contained two equivalents of acid to one of base. The former was, therefore, denominated simply sulphate, the latter *supersulphate* of quinia. A different view has now been generally adopted, according to which the salt formerly considered a supersulphate is in fact strictly neutral, and therefore entitled to the name of sulphate of quinia, while the officinal salt is thought to contain two equivalents of base to one of acid, and is therefore properly a *subsulphate* or *disulphate* of quinia. The latter name has been adopted by the London College. In the U. S., Dublin, and Edinburgh Pharmacopœias, as well as in the French Codex, the original name of sulphate of quinia is still applied to the officinal salt. Hence has arisen a confusion of nomenclature which must be embarrassing to the student. It is the salt formerly called *supersulphate* which remains in the mother waters when an excess of acid is added in the process for procuring the sulphate of quinia. According to M. Baup, it is soluble in 11 parts of water at 54° F., and in its own water of crystallization at the boiling point. It is very soluble in diluted, and somewhat less so in absolute alcohol. It may be obtained by adding to a boiling concentrated solution of the ordinary sulphate, as much sulphuric acid as already exists in the salt, and then evaporating the solution.

Composition. The officinal sulphate of quinia, the subsulphate or disulphate of chemists, is the only one used in medicine, and to this we have allusion in the present work whenever the sulphate of quinia is mentioned without any distinguishing epithet. In the crystalline form it is stated to consist of one equivalent of sulphuric acid 40.1, two equiv. of quinia 329.1, and eight equiv. of water $72 = 441.2$; or, in the hundred parts, of 9.09 of sulphuric acid, 74.59 of quinia, and 16.32 of water. On exposure to the air or to a heat of 212° it effloresces, losing one-half of its water of crystallization, (according to Soubeiran, six equivalents), and at 240° it loses one-half of the remainder, retaining two equivalents or about 4 per cent. of water, of which it cannot be deprived without undergoing decomposition. (*Phillips.*)

Incompatibles and tests. Sulphate of quinia is decomposed by the alkalis and their carbonates, and by the alkaline earths. In solution, it affords white precipitates with potassa, soda, and ammonia, which are partly soluble in an excess of alkali. It is also precipitated by vegetable astringent infusions, the tannic acid of which forms a white insoluble compound with quinia. The soluble salts of lead and of baryta occasion precipitates; and that produced by the salts of baryta is insoluble in the acids. A freshly prepared solution of chlorine, added to a solution of the sulphate of quinia, and followed by the addition of water of ammonia, occasions an emerald-green colour, and, in certain proportions, the deposition of a green precipitate.

Adulterations. The high price of sulphate of quinia has led to various attempts at adulteration. Sulphate of lime, and other alkaline or earthy salts, gum, sugar, mannite, starch, stearin or margarin, caffein, salicin, and sulphate of cinchonia, are among the substances which are said to have been fraudulently added. By attending to the degree of solubility of the sulphate in different menstrua, and to its chemical relations with other substances already described, there can be little difficulty in detecting these adulterations. The presence of any mineral substance not readily volatilizable, may be at once ascertained by exposing the salt to a red heat, which

will completely dissipate the sulphate of quinia, leaving the mineral behind. A volatile ammoniacal salt may be detected by the smell of ammonia emitted upon the addition of potassa. Gum and starch are left behind by alcohol, and fatty matters by water acidulated with sulphuric acid. Sugar and mannite cause a solution of the salt in acidulated water to have a sweet taste after the precipitation of the quinia by an alkaline carbonate. Salicin imparts the property of becoming red upon the contact of sulphuric acid. Caffein alters the degree of solubility in different menstrua. If upon dissolving the salt in acidulated water, precipitating by ammonia, and dissolving the precipitate in boiling alcohol, the alcoholic solution should deposit crystals upon cooling, the presence of cinchonia may be suspected. The Edinburgh College gives the following mode of testing the purity of sulphate of quinia. "A solution of ten grains in a fluidounce of distilled water and two or three drops of sulphuric acid, if decomposed by a solution of half an ounce of carbonate of soda in two waters [twice its weight of water], and heated till the precipitate shrinks and fuses, yields on cooling a solid mass, which when dry weighs 7.4 grains, and in powder dissolves entirely in solution of oxalic acid."

Medical Properties and Uses. Sulphate of quinia produces upon the system, so far as we are enabled to judge by observation, the same effects with Peruvian bark, without being so apt to nauseate and oppress the stomach. (See *Cinchona*.) Its effects upon the brain are even more striking than those of cinchona, probably because it is given in larger proportional doses. Even in the ordinary therapeutical doses, it often produces considerable cerebral disturbance, evinced by a feeling of tightness or distension in the head, ringing, buzzing, or roaring in the ears, hardness of hearing, &c. Some individuals are much more liable to these effects than others, and in some even small doses produce them. A certain degree of this observable action on the brain is rather desirable than otherwise, as the evidence that the medicine is affecting the system. In very large quantities, as from a scruple to a drachm or more, besides the phenomena mentioned, it has been observed to occasion severe headache, vertigo, deafness, diminution or loss of sight, dilated and immovable pupil, loss of speech, general tremblings, intoxication or delirium, coma, and great prostration. In some instances the pulse has been remarkably diminished in frequency, down even to fifty or even a smaller number of beats in the minute. In an instance recorded by Giacomini, in which a man took by mistake about three drachms, the patient became insensible, and some hours afterwards was found by the physician in a state of great general prostration, from which he recovered under the use of laudanum and aromatic waters. (*Annuaire de Thérapeutique* for 1843, p. 176.) Besides its effects on the brain, sulphate of quinia sometimes also occasions great gastric and intestinal irritation, marked by oppression at stomach, nausea, abdominal pains, vomiting, and purging. In general these effects of excessive doses gradually pass off, although partial deafness often continues for several days, and sometimes much longer. It is even said that permanent deafness has resulted. We have seen no well authenticated case of death produced by the direct action of sulphate of quinia in health. Given largely in diseased states it has been the obvious cause of fatal results, not so much however by its peculiar action, as by co-operating with the disease in establishing intense local irritation or inflammation. Though capable, therefore, of doing much mischief if improperly used, sulphate of quinia can scarcely be ranked among the poisons.

From its occasional effect in diminishing the frequency of the pulse and

the general strength, it has been supposed to be essentially sedative in large doses. Such an opinion, unless well founded, might lead to hazardous practice; and the observations hitherto reported are not such as to enable us to come to a just conclusion. In most instances in which the effect was observed the patient was in a morbid state, sometimes labouring under malignant diseases; and in such cases it is well known that powerful stimulants often have the effect of diminishing the frequency of the pulse. In the case observed by Giacomini, the patient was not seen until some hours after taking the sulphate, and might have been in the condition of universal prostration which follows all excessive excitement. In the present state of our knowledge upon the subject, it is safest to consider the sulphate of quinia in a greater or less degree excitant, in whatever dose it may be taken.

Sulphate of quinia may be substituted for cinchona in all diseases to which the latter is applicable; and, in the treatment of intermittents, it has proved so efficacious as to have almost entirely superseded the use of bark. It has the advantage over this remedy, not only that it is more easily administered in large doses, and more readily retained by the stomach, but that in cases which require an impression to be made through the rectum or the skin, it is much more effectual, because, from the smallness of its bulk, it is more readily retained in the former case, and more speedily absorbed in the latter. Still we cannot be certain that there are not other active principles in bark besides the quinia and cinchonia, the latter of which possesses properties analogous to those of the former; nor that the mode of combination in which these principles exist, may not so modify their action as to render them more effectual in certain forms of disease. The question can be solved only by careful and long continued observation. In the mean time, we may resort to the bark if the sulphate of quinia should not answer the ends in view; and instances have occurred, under our own notice, in which it has proved successful in intermittents after the salt has failed.

Sulphate of quinia may be given in pill or solution, or suspended in water by the intervention of syrup and mucilage. The form of pill is usually preferred. (See *Pilulæ Quiniæ Sulphatis*.) The solution may be readily effected by the addition of a little acid of almost any kind to the water. Eight grains of the sulphate will dissolve in a fluidounce of water acidulated with about twelve minims of the diluted sulphuric acid, or aromatic sulphuric acid of the Pharmacopœias; and this is the most eligible mode of exhibiting the medicine in the liquid form. The addition of a small proportion of sulphate of morphia or of laudanum, will often be found advantageous when the stomach is disposed to be sickened, or the bowels to be disturbed by the quinia.

Twelve grains of the sulphate of quinia are equivalent to about an ounce of good bark. The dose varies exceedingly, according to the circumstances of the patient and the object to be accomplished. As a tonic simply, a grain may be given three or four times a day, or more frequently in acute cases. In intermittents, from twelve to twenty-four grains should be given between the paroxysms, divided into smaller or larger doses according to the condition of the stomach, or the length of the intermission. From one to four grains may be given at once, and some even advise the whole amount. In malignant intermittents and remittents the quantity may be increased to thirty grains or even a drachm between the paroxysms. M. Maillot gave one hundred and twenty-eight grains, in the course of a few hours, in a case of malignant fever occurring in Northern Africa, with the happiest results.

(*Bell, in Stokes and Bell's Lectures on Theory and Practice, &c.*) The caution, however, is necessary, not to employ this heroic practice against easily conquerable diseases. When the stomach will not retain the medicine, it may be administered with nearly as much efficacy by enema; from six to twelve grains, with two fluidounces of liquid starch, and from twenty to forty drops of laudanum, being injected into the rectum, in ordinary cases, every six hours. Should circumstances render this mode of application impracticable, an equal quantity, diluted with arrow root or other mild powder, may be sprinkled, at the same intervals, upon a blistered surface denuded of the cuticle. The epigastrium, or the inside of the thighs and arms, would be the proper place for the blister. The sulphate has also been employed by friction in the form of ointment, in cases of malignant intermittent. The ointment should be made by incorporating a saturated alcoholic solution of the salt with lard, and should be applied to the inside of the thighs and arms.

SODA.

Preparations of Soda.

SODÆ CARBONAS EXSICCATUS. U. S. SODÆ CARBONAS EXSICCATA. *Lond.* SODÆ CARBONAS SICCATUM. *Ed., Dub.* *Dried Carbonate of Soda.*

“Take of Carbonate of Soda *a convenient quantity*. Expose it to heat, in a clean iron vessel, until it is thoroughly dried, stirring constantly with an iron spatula; then rub it into powder.” *U. S.*

The *London College* takes a pound of the salt, exposes it to heat in a proper vessel, until it is dried, and, having subjected it to a red heat, rubs it to powder. The *Edinburgh College* heats any convenient quantity in a shallow vessel till it is dry, then urges it with a red heat in a crucible, and reduces it to powder when cold.

“Liquefy the crystals of Carbonate of Soda in a silver crucible over the fire. Then, having increased the heat, stir the liquefied salt, until, by the evaporation of the water, it becomes dry. Reduce the residual salt to fine powder, and keep it in close vessels.” *Dub.*

Carbonate of soda contains ten equivalents of water of crystallization, and, when heated, readily undergoes the watery fusion. Upon continuing the heat, the water is dried off, and a white porous mass remains, which is easily reduced to powder. The London and Edinburgh Colleges expose the dry mass to a red heat before powdering it. Dried carbonate of soda is in the form of a white powder, and differs in no respect from the carbonate, except in being devoid of water of crystallization. (See *Sodæ Carbonas*.)

Medical Properties and Uses. This preparation was introduced into regular practice on the recommendation of Dr. Beddoes, who extolled its virtues in calculous complaints. It is only applicable to the cure of such affections, when dependent on a morbid secretion of uric acid. Its advantage over the common carbonate is that it admits of being made up into pills, in consequence of being in the dried state. As the water of crystallization forms more than half of the carbonate, the dose of the dried salt must be reduced in proportion. From five to fifteen grains may be given three times a day in the form of pill, prepared with soap and aromatics. The general

medical properties of this salt have been given under another head. (See *Sodæ Carbonas.*)

B.

SODÆ CARBONATIS AQUA. *Dub.* *Water of Carbonate of Soda.*

"Take of Carbonate of Soda *any quantity.* Dissolve it in Distilled Water so as to form a solution of the specific gravity 1.024. A solution of this density is obtained by dissolving *an ounce* of Carbonate of Soda in *a pint* of Distilled Water." *Dub.*

This preparation furnishes a solution of carbonate of soda of determinate strength, each fluidounce of which contains half a drachm of the salt. It is convenient for prescribing the alkali in solution, and forming effervescing draughts, each fluidounce being saturated, on an average, by half a fluidounce of lemon juice. The dose is from one to two fluidounces, sufficiently diluted with water, and given two or three times a day. *B.*

SODÆ BICARBONAS. *U.S., Ed., Dub.* SODÆ SESQUICARBONAS. *Lond.* Bicarbonate of Soda. Sesquicarbonate of Soda.

"Take of Carbonate of Soda, in crystals, *a convenient quantity.* Break the crystals in pieces, and put them into a wooden box, having a transverse partition near the bottom pierced with numerous small holes, and a cover which can be tightly fitted on. To a bottle having two tubulures, and half filled with water, adapt two tubes, one connected with an apparatus for generating carbonic acid and terminating under the water in the bottle, the other commencing at the tubulure in which it is inserted, and entering the box by an opening near the bottom, beneath the partition. Then lute all the joints, and cause a stream of Carbonic Acid to pass through the water into the box until the Carbonate of Soda is fully saturated. Carbonic Acid is obtained from Marble by the addition of dilute Sulphuric Acid." *U. S.*

"Fill with fragments of Marble a glass jar, open at the bottom and tubulated at the top; close the bottom in such a way as to keep in the Marble without preventing the free passage of a fluid; connect the tubulature closely by a bent tube and corks with an empty bottle, and this in like manner with another bottle, filled with one part of Carbonate of Soda and two parts of Dried Carbonate of Soda well triturated together; and let the tube be long enough to reach the bottom of the bottle. Before closing the last cork closely, immerse the jar to the top in diluted Muriatic Acid, contained in any convenient vessel; when the whole apparatus is thus filled with carbonic acid gas, secure the last cork tightly; and let the action go on till next morning, or till gas is no longer absorbed by the salt. Remove the damp salt which is formed, and dry it, either in the air without heat, or at a temperature not above 120°." *Ed.*

"Take of Carbonate of Soda *seven pounds;* Distilled Water *a gallon* [Imperial measure]. Dissolve the Carbonate of Soda in the Water, and strain; then pass Carbonic Acid into the solution to saturation, that the salt may subside. Dry this with a gentle heat, after it has been wrapped and pressed in a linen cloth." *Lond.*

"Take of Carbonate of Soda *two parts;* Water *five parts.* Dissolve, and in a proper apparatus, expose the solution to a stream of Carbonic Acid gas, evolved during the solution of White Marble in dilute Muriatic Acid, until it ceases to absorb gas; and let it remain at rest that crystals may be formed. Then, with a heat not exceeding 120°, evaporate the solution that

crystals may again be formed, which are to be mixed with those first obtained, dried, and preserved in a close vessel." *Dub.*

The object of these processes is to combine the alkali with an additional equivalent of carbonic acid, whereby it becomes converted into the bicarbonate. The official processes are different, and, therefore, require a separate notice.

The process adopted in the last U. S. Pharmacopœia, is that which has been practised for many years in the United States, and which was described in 1830, by Dr. Franklin R. Smith, in the first volume of the Journal of the Philadelphia College of Pharmacy. This process is attributed to Dr. Smith by Soubeiran, who characterizes it as the best that can be employed. (*Nouv. Traité de Pharm.*) It was adopted in the French Codex on its revision of 1837. A stream of carbonic acid is passed into a suitable vessel, containing the crystallized carbonate placed on a diaphragm, pierced with numerous holes. As the bicarbonate combines with much less water of crystallization than is contained in the carbonate, it follows that, during the progress of the saturation of the carbonate, a considerable quantity of water is liberated. This water would finally dissolve the bicarbonate formed, were it not for the diaphragm, through which it is allowed to drain off, holding in solution a part of the carbonate. When the saturation is completed, the pieces of crystals, still supported on the diaphragm, are found to have retained their original form, but to have become of a porous and loose texture.

The process newly adopted in the last Edinburgh Pharmacopœia is that of Berzelius, described in former editions of this Dispensatory. In the U. S. process, the excess of water over the quantity necessary for the bicarbonate, is allowed to drain off; but it holds a certain portion of carbonate in solution which thus escapes the action of the carbonic acid. To avoid this result it is only necessary to prepare a carbonate, containing just sufficient water of crystallization to accommodate the bicarbonate; and the process recommended by Berzelius accomplishes this purpose. Thus the salt which he prepares to be submitted to the stream of carbonic acid, is an intimate mixture, in fine powder, of four parts of effloresced carbonate, with one of the crystallized salt. The proportion adopted by the Edinburgh College is different; namely, two parts of the dried carbonate to one of the crystallized carbonate, and is such as to afford a slight excess of water over what is required to constitute the bicarbonate. Hence the Edinburgh process furnishes a damp salt, which is dried in the air without heat, or at a temperature not exceeding 120° . The apparatus employed by the College for generating the carbonic acid is precisely the self-regulating reservoir devised by Dr. Hare on the principle of Gay-Lussac's. The empty bottle, placed between the generating apparatus and that containing the salt, is intended to detain any impurity which may be carried over with the stream of carbonic acid.

The London College employs the old process of dissolving the carbonate in water before submitting it to the action of carbonic acid. The solution, when saturated, lets fall the sparingly soluble bicarbonate in minute crystals, which are pressed in a linen cloth, and dried by a gentle heat. In this process, the mother water is not evaporated, although it contains a considerable portion of bicarbonate. The reason of this omission is, no doubt, the difficulty of applying heat in such a manner as not to decompose the salt. The Dublin process is similar to the London. The points of difference are that a weaker alkaline solution is employed, and that the mother water is evaporated at a heat not exceeding 120° for the production of a

second crop of crystals. Both these processes are unproductive, and, besides, furnish an imperfect bicarbonate. At present they are superseded by processes similar to those of the U. S. and Edinburgh Pharmacopœias.

Properties, &c. As obtained by the U. S. formula, bicarbonate of soda is in opaque, porous masses, made up of numerous, aggregated crystalline grains, and having a snow-white colour. For the convenience of the apothecary these masses are reduced to powder. As procured by the Edinburgh process, it is in small, white, opaque, irregular scales. The London and Dublin preparation is in minute, colourless, indistinct crystals. Bicarbonate of soda is permanent in the air, and slightly alkaline to the taste and to turmeric paper. It is soluble in thirteen parts of cold water. When the solution is exposed to heat, the salt gradually parts with carbonic acid, and, at the temperature of 212° , is converted into sesquicarbonate. At a red heat, the water of crystallization and the second equivalent of carbonic acid are expelled, and the anhydrous monocarbonate is left. One eq., or 84.54 parts of the crystallized bicarbonate, should lose, by complete decomposition by dilute sulphuric acid, two eqs. or 44.24 parts of carbonic acid. The salt is seldom so perfect as to withstand this test; as good commercial samples generally contain from two to three per cent. of carbonate. The presence of this impurity may be known by a decided alkaline taste and reaction, by a cold solution of the salt yielding a precipitate with sulphate of magnesia, and by a solution in forty parts of water, yielding, without agitation, an orange-coloured or reddish-brown precipitate with corrosive sublimate; whereas the pure salt produces a slight opalescence only with the latter test. This test is adopted in the Edinburgh Pharmacopœia, and, according to Dr. Christison, readily detects one per cent. of carbonate. The pure bicarbonate is not precipitated by chloride of platinum, nor, when supersaturated with nitric acid, by chloride of barium or nitrate of silver. The non-action of these tests proves the absence of salts of potassa, and of sulphates and chlorides. The incompatibles of this salt are the same as those of the carbonate, except sulphate of magnesia in the cold, which decomposes the carbonate, but not the bicarbonate.

Composition. Bicarbonate of soda, when perfect, consists of two eqs. of carbonic acid 44.24, one of soda 31.3, and one of water 9=84.54; but, as found in the shops, it seldom contains so large a proportion of carbonic acid. The London College calls the product of its formula, a sesquicarbonate; but, though it contains less carbonic acid than the bicarbonate, it by no means has a constant composition corresponding with the sesquisalt. The London name for this salt should, therefore, be abandoned, as an unsuccessful attempt to express its composition when imperfectly made. It is admitted that the bicarbonate is now made nearly perfect on a large scale; and the U. S. and Edinburgh processes furnish a pure salt.

Medical Properties and Uses. This salt has the general medical properties of the carbonate; but, from its mild taste and less irritating qualities, proves more acceptable to the palate and stomach. It is often resorted to in calculous cases, characterized by predominant uric acid. When the carbonate is given in these cases, its continued use is liable to induce phosphatic deposits, after the removal of the uric acid. According to D'Arcet, who made the observation at the springs of Vichy, this objection does not lie to the bicarbonate, especially when taken in carbonic acid water; for this salt, by its superabundant acid, has the power of maintaining the phosphates in solution, even after the alkali has caused the uric acid to disappear. The same remark is applicable to the bicarbonate of potassa. Bicarbonate of soda has been given in infantile croup, with apparent advantage

in promoting the expectoration of the false membrane, in the dose of a grain every five minutes, dissolved in milk and water. The dose for an adult is from ten grains to a drachm, and is taken most conveniently in a glass of carbonic acid water. This salt is principally consumed in making what are called soda and Seidlitz powders. (See page 52.) It is sometimes made into lozenges. (See *Trochisci Sodæ Bicarbonatis*.)

Off. Prep. Liquor Sodæ Effervescens, *Lond., Ed.*; Pulveres Effervescentes, *Ed.*; Trochisci Sodæ Bicarbonatis, *Ed.* B.

LIQUOR SODÆ EFFERVESCENS. *Lond.* SODÆ AQUA EFFERVESCENS. *Ed.* *Effervescing Solution of Soda.*

“Take of Sesquicarbonate of Soda *a drachm*; Distilled Water *a pint* [Imperial measure]. Dissolve the Carbonate of Soda in the Water, and pass into it, compressed by force, more Carbonic Acid than is sufficient for saturation. Keep the solution in a well-stopped vessel.” *Lond.*

The *Edinburgh* formula corresponds with the above.

This is merely a solution of bicarbonate of soda in carbonic acid water, in the proportion of three grains to the Imperial fluidounce. Such a solution, however, is not a proper object of officinal direction. The names given to it are incorrect. Indeed, the authors of the London Pharmacopœia appear to have been undecided what to call their preparation; as they have denominated it by another name, “Sodæ Carbonatis Liquor Effervescens,” in their “Notes.” B.

AQUA CARBONATIS SODÆ ACIDULA. *Dub.* *Acidulous Water of Carbonate of Soda.*

“Take of Carbonate of Soda *any quantity*. Dissolve it in such a quantity of Water that each *pint* may contain *a drachm* of Carbonate of Soda. Then, in an apparatus adapted for retaining the gas, subject it to a stream of carbonic acid gas, evolved during the solution of pieces of White Marble in Muriatic Acid, diluted with six times its weight of water, until the carbonic acid is in excess.” *Dub.*

This preparation is a solution of carbonate of soda in carbonic acid water. As, however, an excess of carbonic acid is passed into the solution, the alkali may be presumed to become a bicarbonate; and if so, the preparation is equivalent to that last described. It corresponds with the solution formerly called *soda water*, which was made by impregnating, under strong pressure, a weak solution of carbonate of soda with carbonic acid; but at present, this name is applied, in popular language, to carbonic acid water without soda. This solution, however, is superfluous as an officinal preparation; as it may be made extemporaneously by adding any desired quantity of carbonate of soda to carbonic acid water. B.

LIQUOR SODÆ CHLORINATÆ. *U.S., Lond.* *Solution of Chlorinated Soda. Solution of Chloride of Soda. Labarraque's Disinfecting Soda Liquid.*

“Take of Chlorinated Lime *a pound*; Carbonate of Soda *two pounds*; Water *a gallon and a half*. Dissolve the Carbonate of Soda in three pints of the Water, with the aid of heat. To the remainder of the Water add, by small portions at a time, the Chlorinated Lime previously well triturated, stirring the mixture after each addition. Set the mixture by for several hours that the dregs may subside; then decant the clear liquid, and mix it with the solution of Carbonate of Soda. Lastly, decant the clear liquor from the precipitated carbonate of lime, pass it through a linen cloth, and keep it in bottles secluded from the light.” *U. S.*

“Take of Carbonate of Soda *a pound*; Distilled Water *forty-eight fluid-ounces* [Imperial measure]; Chloride of Sodium *four ounces*; Binoxide of Manganese *three ounces*; Sulphuric Acid *four ounces*. Dissolve the Carbonate of Soda in two pints of Water. Then put the Chloride of Sodium and Binoxide of Manganese, rubbed to powder, into a retort; and add to them the Sulphuric Acid, previously mixed with three fluidounces of Water and cooled. Heat the mixture, and pass the chlorine first through five fluidounces of Water, and afterwards into the solution of Carbonate of Soda above directed.” *Lond.*

This solution was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris. It was afterwards used as a medicine, and found to possess valuable properties. The process of the U. S. Pharmacopœia is that of Payen, which was adopted in the French Codex of 1837. It consists in decomposing a solution of carbonate of soda by one of chlorinated lime. Carbonate of lime is precipitated, and the chlorinated soda remains in solution. The proportion employed gives an excess of carbonate of soda, the presence of which renders the solution more permanent. The *London* process is that of Labarraque. All the chlorine generated from the prescribed quantity of the materials for forming that gas, is passed into the solution of carbonate of soda; and when the gas is limited to this quantity, no carbonic acid is disengaged. The chlorine is first passed through water to free it from muriatic acid, which, if suffered to come over, would convert the alkali into common salt.

Properties. The U. S. solution is a colourless liquid. The *London* preparation has a pale yellow colour, and a sharp, saline, astringent taste. When it is boiled, chlorine is not given off, nor is its bleaching property sensibly impaired; and, when carefully evaporated, a mass of damp crystals is obtained, which, when redissolved in water, possess the properties of the original liquid. Both solutions contain an excess of carbonated alkali, and, therefore, have an alkaline reaction. Hence they are precipitated by lime-water, which throws down carbonate of lime. They both decolorize the solution of sulphate of indigo, and emit a slight odour of chlorine. When dilute muriatic acid is added to them, carbonic acid and chlorine are extricated. Exposed to the air, carbonic acid is absorbed, and chlorine slowly evolved. It is on this property of gradually evolving chlorine that their disinfecting power depends.

Nature and Composition. The chemical nature of these solutions is different. Assuming the chlorinated lime to be essentially hypochlorite of lime with chloride of calcium (see page 151), the U. S. solution will contain *hypochlorite of soda* with *chloride of sodium*. Besides these there will be present more or less *carbonate of soda*, according as there happens to be in the chlorinated lime more or less chlorine to decompose it. In all cases, however, there will be an excess of carbonate; as the best chlorinated lime does not contain sufficient chlorine to effect its entire decomposition, in the proportion in which it is taken in the formulæ. The constitution of the *London* preparation is more complicated. As it is a peculiarity in its formation that no carbonic acid is evolved, it is necessary to assume the presence of all the carbonic acid of the carbonate of soda; and hence it is considered to be a combination of *hypochlorite of soda*, *chloride of sodium*, and *bicarbonate of soda*. The reaction is supposed to take place between four eqs. of carbonate of soda and two of chlorine. By a transfer of carbonic acid from two eqs. of carbonate to the remaining two eqs. of the same salt, two eqs. of bicarbonate are formed, and two of soda left. The sodium and oxygen of one eq. of soda, unite, each, with one eq. of chlorine, so as to

form one eq. of chloride of sodium, and one of hypochlorous acid. This acid then unites with the remaining eq. of soda to form hypochlorite of soda. The view here taken makes these solutions analogous in constitution; but differing in one containing the carbonate, the other the bicarbonate of soda. In the London preparation, half the soda remains carbonated; in the U. S. solution, from a half to a third, according to the quality of the chlorinated lime used. It is not easy to compare these solutions as to their chlorine strength; but it may be roughly estimated that the London preparation is between two and three times as strong as that of the U. S. Pharmacopœia. The London solution, though made on Labarraque's plan, is considerably stronger than his preparation; for the London College dissolves the carbonate in about three times its weight of water, before transmitting the chlorine; whereas Labarraque dissolved it in four times its weight.

Medical Properties and Uses. Solution of chlorinated soda is stimulant, antiseptic, and resolvent. Internally it has been employed in diseases termed *putrid* or *malignant*, as typhus fever, scarlatina maligna, &c. The conditions which indicate the propriety of its use are great prostration of strength, fetid evacuations, and dry and furred tongue. Under such circumstances it promotes urine, creates a moisture on the skin, and improves the secretions and evacuations. It has also been given in dysentery accompanied with peculiarly fetid stools, in dyspepsia attended with putrid eructations, and in glandular enlargements and chronic mucous discharges. Other diseases in which it has been recommended, are intermittents as a substitute for quinia, secondary syphilis, scrofula, bilious disorders as a substitute for chlorine, and chronic diseases of the skin. M. Chailly speaks in praise of it in suppressed or deficient menstruation. In asphyxia from sulphuretted hydrogen it forms, like chlorinated lime, an efficacious antidote. The dose of the U. S. solution is from thirty drops to a teaspoonful, given in a cupful of water or mild aqueous liquid, and repeated every two or three hours.

As a local remedy it is susceptible of many valuable applications, and acts not merely in its quality of disinfectant, but as a peculiar stimulant to the living tissues. It is found useful in all external affections attended with fetor, such as gangrenous, cancerous, scrofulous, and syphilitic ulcers, ulceration of the gums, carbuncle, ozæna, mortification, putrid sorethroat, &c. In these cases it is applied in a more or less dilute state, as a gargle, wash, ingredient of poultices, or imbibed by lint. In the sloughing of the fauces attendant upon severe cases of scarlatina, Dr. Samuel Jackson, late of Northumberland, found it efficacious, used as a gargle, or injected into the throat. (*Am. Journ. of Med. Sci.* xxii. 45.) In the sore mouth from pyalism, it forms a good mouth-wash, when diluted with eight parts or more of water. In fetid discharges from the vagina, uterus, and bladder, it has been employed with advantage as an injection, diluted with from fifteen to thirty parts of water for the vagina and uterus, and with sixty parts when the object is to wash out the bladder by means of a double cannula. The solution of chlorinated soda has also been applied successfully to burns, and to cutaneous eruptions, particularly psoriasis, tinea capitis, scabies, and obstinate herpetic affections. In these cases it is diluted with from ten to thirty parts of water, the strength varying according to circumstances. For the cure of sore nipples, Dr. Chopin found nothing so successful as frequently repeated lotions with this solution.

Solution of chlorinated soda is a powerful disinfectant, possessing in this respect the same general properties as chlorinated lime. It is, however, much better suited for disinfecting operations than the latter; as it does not,

when exposed to the air, become covered with a crust of carbonate of lime, an objection to which the solution of the bleaching salt is liable. Yet the comparative expensiveness of chlorinated soda will restrict its use to disinfecting operations on a small scale. In the bed-chambers of the sick, especially with infectious diseases, it will be found highly useful, sprinkled on the floor or bed, and added to the vessels intended to receive the excretions. In short it is applicable to most of the disinfecting purposes detailed under the head of *Calx Chlorinata*, to which title the reader is referred. B.

SODÆ ET POTASSÆ TARTRAS. *U.S., Dub.* SODÆ POTASSIO-TARTRAS. *Lond.* POTASSÆ ET SODÆ TARTRAS. *Ed.* *Tartrate of Potassa and Soda.* *Tartarized Soda.* *Rochelle Salt.*

“Take of Carbonate of Soda *a pound*; Bitartrate of Potassa [cream of tartar], in powder, *sixteen ounces*; boiling Water *five pints*. Dissolve the Carbonate of Soda in the Water, and gradually add the Bitartrate of Potassa. Filter the solution, and evaporate until a pellicle forms; then set it aside to crystallize. Pour off the liquor, and dry the crystals on bibulous paper. Lastly, again evaporate the liquor, that it may furnish more crystals.” *U. S.*

The *London* and *Edinburgh* processes correspond with the above.

“Take of Carbonate of Soda *five parts*; Bitartrate of Potassa, in very fine powder, *seven parts*; boiling Water *fifty parts*. Dissolve the Carbonate of Soda in the Water, and gradually add the Bitartrate of Potassa. Filter the liquor through paper, evaporate, and set it aside, so that on slow cooling crystals may form.” *Dub.*

This is a double salt, consisting of tartrate of potassa combined with tartrate of soda. The theory of its formation is exceedingly simple, being merely the saturation of the excess of acid in the bitartrate of potassa by carbonate of soda, the carbonic acid of which is extricated with effervescence. The proper quantities of the materials for mutual saturation are 143·42 parts of carbonate to 189·11 of bitartrate, or one eq. of each. This gives the ratio of 10 to 13·1. The proportion adopted in the *U. S.*, *London*, and *Edinburgh Pharmacopœias*, is as 10 to 13·33, which is very near the theoretical quantities. As the salts employed are apt to vary in composition and purity, the carbonate from the presence of more or less water of crystallization, and the bitartrate from that of tartrate of lime, it is, perhaps, best in all cases, after indicating the nearest average proportion as a general guide, to present to the operator the alternative of using the cream of tartar to the point of exact saturation.

Berzelius states that this salt may be formed by saturating six parts of cream of tartar by means of carbonate of potassa, and then adding to the resulting tartrate a solution of five parts of crystallized sulphate of soda. On evaporation, sulphate of potassa will first crystallize, and afterwards the tartrate of potassa and soda. The rationale is obvious.

Properties. Tartrate of potassa and soda is in the form of colourless, transparent, slightly efflorescent crystals, often very large, and having the shape, when carefully prepared, of right prisms, with ten or twelve unequal sides. As ordinarily crystallized, they are generally in half prisms, as if split in the direction of their axis. Its taste is saline and slightly bitter. It dissolves in five times its weight of cold water, and in much less boiling water. Any undissolved residue is impurity, probably tartrate of lime or bitartrate of potassa, or both. When exposed to a strong heat, the tartaric acid is destroyed, and a mixture of the carbonates of potassa and soda is left. It sometimes contains tartrate of lime, which may be removed by solution and

crystallization; but when the crystals are large and well defined, it may be assumed to be pure. It is incompatible with most acids, and with all acidulous salts except the bitartrate of potassa. It is also decomposed by the acetate and subacetate of lead, by the soluble salts of lime, and by those of baryta, unless the solution of the tartrate be considerably diluted. The way in which acids act in decomposing it, is by combining with the soda, and throwing down bitartrate of potassa as a crystalline precipitate. This double salt was discovered by Seignette, an apothecary of Rochelle; and hence it is frequently called *Seignette's salt*, or *Rochelle salt*.

Composition. Tartrate of potassa and soda consists of two eqs. of tartaric acid 132·96, one of potassa 47·15, one of soda 31·3, and eight of water 72=283·41; or, considered as a double salt, of one eq. of tartrate of potassa 113·63, and one of tartrate of soda 97·78, with the same quantity of water.

Medical Properties and Uses. This salt is a mild, cooling purgative, well suited to delicate and irritable stomachs, being among the least unpalatable of the neutral salts. As it is not incompatible with tartar emetic, it may be associated with that salt in solution. It is an ingredient in the effervescing aperient called Seidlitz powders, the composition of which is given at page 52. The dose is from half an ounce to an ounce.

B.

SODÆ MURIAS PURUM. *Ed.* Pure Muriate of Soda. *Pure Chloride of Sodium.*

“Take any convenient quantity of Muriate of Soda; dissolve it in boiling water; filter the solution, and boil it down over the fire, skimming off the crystals which form. Wash the crystals quickly with cold water and dry them.” *Ed.*

This new formula of the Edinburgh College is unnecessary. If commercial samples of chloride of sodium cannot be found pure enough to form muriatic acid, the salt may be purified as a preparatory step to the process for obtaining that acid; as is ordered by the College in the formula for *Acidum Muriaticum Purum*, where the directions for purifying the salt are unnecessarily repeated, after the admission of a distinct formula for that purpose. Pure muriate of soda is ordered by the College, with needless refinement, as an ingredient in the compound saline powder.

Off. Prep. Pulvis Salinus Compositus, *Ed.*

B.

SODÆ PHOSPHAS. *U.S., Lond., Ed., Dub.* Phosphate of Soda.

“Take of Bone, burnt to whiteness and powdered, *ten pounds*; Sulphuric Acid *six pounds*; Carbonate of Soda *a sufficient quantity*. Mix the powdered Bone with the Sulphuric Acid in an earthen vessel; then add a gallon of water, and stir them well together. Digest for three days, occasionally adding a little water to replace that which is lost by evaporation, and frequently stirring the mixture. At the expiration of this time, pour in a gallon of boiling water, and strain through linen, gradually adding more boiling water, until the liquid passes nearly tasteless. Set by the strained liquor that the dregs may subside, from which pour off the clear solution, and boil it down to a gallon. To this solution, poured off from the dregs and heated in an iron vessel, add by degrees the Carbonate of Soda previously dissolved in hot water, until effervescence ceases, and the phosphoric acid is completely neutralized; then filter the liquor, and set it aside to crystallize. Having removed the crystals, add, if necessary, a small quantity of Carbonate of Soda to the liquor, so as to render it slightly alka-

line; then alternately evaporate and crystallize, so long as crystals are produced. Lastly, preserve the crystals in a well stopped bottle." *U. S.*

The *Edinburgh College* takes the same materials and in the same proportion, and proceeds substantially as above. The two pints and four fluidounces [Imperial measure] of sulphuric acid ordered by the College, weigh six pounds. The *London College* made this salt official for the first time in its Pharmacopœia for 1836, but has placed it in the list of the *Materia Medica*.

"Take of burnt Bones, in powder, *ten parts*; Commercial Sulphuric Acid *seven parts*. Mix the powder, in an earthen vessel, with the Sulphuric Acid, add gradually *seven parts* of water, and stir the mixture. Digest for three days, occasionally adding more water to prevent the mixture from becoming dry, and continue the stirring: then add *seven parts* of boiling water, and strain through linen, repeatedly pouring on boiling water, until all the acid is washed out. Set the liquor by that the dregs may subside, from which pour it off when clear, and reduce it by evaporation to one-half. Then add *eight parts* of Carbonate of Soda, dissolved in hot water, and filter; and by alternate evaporation and refrigeration, let crystals be formed, which are to be kept in a well-stopped vessel. If the salt be not sufficiently pure, dissolve it again in water and recrystallize." *Dub.*

The incombustible part of bones, or bone-earth, is obtained by burning them to whiteness, and consists of a peculiar phosphate of lime, called bone-phosphate, associated with some carbonate of lime, &c. (See *Os.*) When this is mixed with sulphuric acid, the carbonate of lime is entirely decomposed, giving rise to effervescence. The phosphate of lime undergoes partial decomposition; the greater part of the lime being detached, precipitates as sulphate of lime, while the phosphoric acid, set free, combines with the undecomposed portion of the phosphate, and remains in solution as a superphosphate of lime, holding dissolved a certain portion of the sulphate of lime. In order to separate the superphosphate from the precipitated mass of sulphate of lime, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as superphosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of superphosphate of lime, are mixed and allowed to stand, and by cooling a portion of sulphate of lime is deposited, which is got rid of by decantation. The bulk of the liquid is now reduced by evaporation, and, from the diminution of the water, a fresh portion of sulphate of lime is deposited, which is separated by subsidence and decantation as before. The superphosphate of lime is now saturated by means of carbonate of soda. The carbonic acid is extricated with effervescence, and the alkali, combining with the *excess* of acid of the superphosphate, generates phosphate of soda; while the superphosphate of lime, by the loss of its excess of acid, becomes the neutral phosphate, and precipitates. This precipitate is next separated by a new filtration; and the filtered liquor, consisting of the solution of phosphate of soda, is evaporated so as to crystallize.

In the *U. S.* and *Edinburgh* process, the calcined bone is to the acid as 10 to 6; in the *Dublin* process as 10 to 7. The proportion recommended by *Berzelius* is intermediate—as 10 to 6.66. The acid, in the official processes, is added to the calcined bone in the concentrated state, and afterwards diluted with more or less water. In the process given by *Berzelius* it is first diluted with twelve times its weight of water. The *Dublin College* prescribes the quantity of carbonate of soda to effect the saturation; but the exact quantity cannot be known beforehand, and must vary under

different circumstances. All the writers state that this salt crystallizes more readily by allowing its solution to be slightly alkaline; and a remarkable fact is that a neutral solution, when it crystallizes, leaves a supernatant liquid which is slightly acid and uncrystallizable. Hence it is unnecessary, after getting each successive crop of crystals, to render the mother water neutral or slightly alkaline, before it will furnish an additional quantity.

M. Funcke, a German chemist, has given the following method for obtaining phosphate of soda, which is stated to be cheaper and more expeditious than the process above described. Add to the powdered calcined bone, diffused in water, sufficient dilute sulphuric acid to decompose all the carbonate of lime which it contains. As soon as the effervescence has ceased, the matter is acted on with nitric acid, which dissolves the phosphate of lime, and leaves the sulphate. The nitric solution of the phosphate is then treated with sulphate of soda, equal in quantity to the bone employed; and after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, sulphate of lime and phosphate of soda are formed, the latter of which is then separated from the sulphate by the action of water, and crystallized in the usual manner.

Properties, &c. Phosphate of soda is in large, colourless crystals, which are transparent at first, but quickly effloresce and become opaque when exposed to the air, and which have the shape of oblique rhombic prisms. It possesses a pure saline taste, resembling that of common salt. With tests it displays a slight alkaline reaction. It dissolves in four parts of cold water, and two of boiling water, but is insoluble in alcohol. Before the blowpipe it first undergoes the aqueous fusion, and afterwards, at a red heat, melts into a globule of limpid glass, which becomes opaque on cooling. It is not liable to any adulterations, but sometimes contains carbonate of soda, from this salt being added in excess; in which case it will effervesce with acids. If it contain sulphate of soda, or any other soluble sulphate, the precipitate caused by chloride of barium will be a mixture of sulphate and phosphate of baryta, and will not be totally soluble in nitric acid. If a chloride be present, the *yellow* precipitate caused by nitrate of silver will be a mixed one of chloride and phosphate of silver, not entirely soluble in the same acid. It is incompatible with soluble salts of lime, with which it gives a precipitate of phosphate of lime, and with neutral metallic solutions. Phosphate of soda is found in several of the animal secretions, particularly the urine. When crystallized it consists of one eq. of phosphoric acid 71·4, two of soda 62·6, and twenty-five of water $225=359$. When heated gently, it loses twenty-four eqs. of water, retaining one which acts the part of a base. At a red heat the remaining eq. of water is driven off, and the salt is altered in its properties, and becomes *pyrophosphate of soda*, which is characterized by giving a *white* precipitate with nitrate of silver.

Medical Properties and Uses. This salt was introduced into regular practice about the year 1800, on the recommendation of Dr. Pearson, of London. It is a mild purgative, and, from its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. The dose is from one to two ounces, and is best given in gruel or weak broth, to which it communicates a taste, as if seasoned with common salt. Heretofore its expensiveness, compared with the cost of other saline purgatives, has prevented it from coming into general use.

Off. Prep. Ferri Phosphas, *U. S.*

SPIRITUS. U.S., Lond., Dub.

Spirits. Ed.

Spirits, according to the Pharmacopœia of the United States, are alcoholic solutions of volatile principles, obtained by distillation. They are prepared chiefly from aromatic vegetable substances, the essential oils of which rise with the vapour of alcohol, and condense with it in the receiver. Some of the oils, however, will not rise at the temperature of boiling alcohol, but may be distilled with water. In this case it is necessary to employ proof spirit or diluted alcohol, with the water of which the oil comes over in the latter part of the process. As the proof spirit of the shops is often impregnated with foreign matters, which give it an unpleasant flavour, it is better to use alcohol which has been carefully rectified, and to dilute it with the due proportion of water, as directed by the U. S. Pharmacopœia. In preparing the spirits, care should be taken to avoid the colour and empyreumatic flavour arising from the decomposition of the vegetable matter by heat. Sufficient water must, therefore, be added to cover the vegetable matter after the alcohol shall have been distilled; and, as a general rule, the heat should be applied by means of a water-bath, or of steam. It is proper that the aromatic should be macerated for some days with the alcohol, before being submitted to distillation; as the oil, being thus dissolved, rises more readily with the spirituous vapour than when confined in the texture of the vegetable. It is necessary, during the process, frequently to renew the water in the refrigeratory, as otherwise a considerable portion of the vapour will escape condensation and be lost. A good apparatus for the purpose is described and figured in page 772.

The aromatic spirits are used chiefly to impart a pleasant odour and taste to mixtures, and to correct the nauseating and griping effects of other medicines. They serve also as carminatives in flatulent colic, and agreeable stimulants in debility of stomach; but their frequent use may lead to the formation of intemperate habits, and should, therefore, be avoided. W.

SPIRITUS ANISI. Lond. Spirit of Aniseed.

“Take of Anise [seeds], bruised, *ten ounces*; Proof Spirit *a gallon* [Imperial measure]; Water *two pints* [Imperial measure]. Mix them; then with a gentle fire, distil a gallon.” Lond.

SPIRITUS ANISI COMPOSITUS. Dub. Compound Spirit of Aniseed.

“Take of Anise Seeds, bruised, Angelica Seeds, bruised, each, *half a pound*; Proof Spirit *a gallon*; Water *sufficient to prevent empyreuma*. Macerate for twenty-four hours, and distil a gallon.” Dub.

The dose of this and the preceding preparation, as stomachics and carminatives, is one or two fluidrachms. The compound spirit is a simplification of the Irish *usquebaugh*. W.

SPIRITUS ARMORACIÆ COMPOSITUS. Lond., Dub. Compound Spirit of Horse-radish.

“Take of Horse-radish [root], sliced, Dried Orange Peel, each, *twenty ounces*; Nutmeg, bruised, *five drachms*; Proof Spirit *a gallon* [Imperial measure]; Water *two pints* [Imp. measure]. Mix them; then, with a slow fire, distil a gallon.” Lond.

The Dublin College takes of horse-radish and orange peel, each, *a pound*,

bruised nutmeg *half an ounce*, proof spirit *a gallon*, and water *sufficient to prevent empyreuma*; macerates for twenty-four hours, and distils a gallon.

This may be used advantageously as an addition to diuretic remedies, in dropsy attended with debility, especially in the cases of drunkards. The dose is from one to four fluidrachms.

Off. Prep. Infusum Armoraciæ Compositum, *Lond.*

SPIRITUS CARUI. *Lond., Ed., Dub. Spirit of Caraway.*

"Take of Caraway [seeds], bruised, *twenty-two ounces*; Proof Spirit *a gallon* [Imperial measure]; Water *two pints* [Imperial measure]. Mix them; then with a slow fire distil a gallon." *Lond.*

"Take of Caraway Seeds, bruised, *a pound*; Proof Spirit *a gallon*; Water *sufficient to prevent empyreuma*. Macerate for twenty-four hours, and distil a gallon." *Dub.*

"Take of Caraway, bruised, *half a pound*; Proof Spirit *seven pints* [Imperial measure]. Macerate for two days in a covered vessel; add a pint and a half [Imp. meas.] of water; and distil off seven pints." *Ed.*

The dose as a carminative is one or two fluidrachms.

SPIRITUS CASSIÆ. *Ed. Spirit of Cassia.*

"Take of Cassia, in coarse powder, *one pound*. Proceed as for the spirit of caraway." *Ed.* (See *Spiritus Carui*.)

This is essentially the same as the spirit of cinnamon.

SPIRITUS CINNAMOMI. *Lond., Ed., Dub. Spirit of Cinnamon.*

"Take of Oil of Cinnamon *two drachms*; Proof Spirit *a gallon* [Imperial measure]; Water *a pint* [Imperial measure]. Mix them; then with a slow fire distil a gallon." *Lond.*

"Take of Cinnamon Bark, bruised, *a pound*; Proof Spirit *a gallon*; Water *sufficient to prevent empyreuma*. Macerate for twenty-four hours, and distil a gallon." *Dub.*

By the *Dublin College* the spirit is also prepared by distilling together *six scruples* of the oil, and *a gallon* of proof spirit. The *Edinburgh College* prepares it from *a pound* of cinnamon, in coarse powder, in the same manner as spirit of caraway. (See *Spiritus Carui*.)

The spirit of cinnamon is an agreeable aromatic cordial, and may be given in debility of the stomach in the dose of one or two fluidrachms.

Off. Prep. Infusum Digitalis, *Ed.*; Infusum Rhei, *Ed.*; Mistura Cretæ, *Ed.*

W.

SPIRITUS JUNIPERI COMPOSITUS. *U.S., Lond., Ed., Dub. Compound Spirit of Juniper.*

"Take of Juniper [berries], bruised, *a pound*; Caraway [seeds], bruised, Fennel-seed, bruised, each, *an ounce and a half*; Diluted Alcohol *a gallon*; Water *two pints*. Macerate the Juniper, Caraway, and Fennel-seed in the Diluted Alcohol for twenty-four hours; then add the Water, and with a slow fire distil a gallon." *U.S.*

"Take of Juniper Fruit, bruised, *fifteen ounces*; Caraway [seeds], bruised, Fennel [seeds], bruised, each, *two ounces*; Proof Spirit *a gallon* [Imperial measure]; Water *two pints* [Imperial measure]. Mix them; then with a slow fire distil a gallon." *Lond.*

The *Dublin* and *Edinburgh* processes are essentially the same with that of the *U.S. Pharmacopœia*; the *Edinburgh* directing *seven pints* [Imp. meas.] of Proof Spirit, and *two pints* [Imp. meas.] of water, macerating for two days, and distilling seven Imperial pints.

This spirit is a useful addition to diuretic infusions and mixtures in debilitated cases of dropsy. The dose is from two to four fluidrachms.

Off. Prep. Mistura Creasoti, *Ed.* W.

SPIRITUS LAVANDULÆ. *U. S., Lond., Ed., Dub.* Spirit of Lavender.

“Take of Fresh Lavender [flowers] *two pounds*; Alcohol *a gallon*; Water *two pints*. Mix them, and with a slow fire distil a gallon.” *U. S.*

The *London College* takes *two pounds and a half* of the fresh flowers, *a gallon* [Imperial measure] of rectified spirit, and *two pints* of water; mixes them; and distils a gallon. The *Dublin College* employs *two pounds* of the flowers, *a gallon* of proof spirit, and sufficient water to prevent empyreuma; macerates for twenty-four hours; and distils five pints. The *Edinburgh College* takes *two pounds and a half* of the fresh flowers, and *a gallon* [Imp. meas.] of rectified spirit; mixes them, and with the heat of a vapour-bath distils seven pints.

The *Dublin* process, in which proof spirit is employed, is said to yield a product less highly impregnated with the oil of lavender than the others. Mr. Brande asserts that the dried flowers produce as fragrant a spirit as the fresh. Spirit of Lavender is used chiefly as a perfume, and as an ingredient in other preparations. The perfume usually sold under the name of *lavender water* is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Mr. Brande as one of the most approved recipes for preparing it. “Take of rectified spirit of wine five gallons, essential oil of lavender twenty ounces, essential oil of bergamot five ounces, *essence of ambergris* (made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol) half an ounce. Mix.”

Off. Prep. Linimentum Camphoræ Compositum, *Lond., Dub.*; Mistura Ferri Composita, *U. S.*; Spiritus Lavandulæ Compositus, *U. S., Lond., Ed., Dub.* W.

SPIRITUS LAVANDULÆ COMPOSITUS. *U. S., Ed., Dub.*
TINCTURA LAVANDULÆ COMPOSITA. *Lond.* Compound Spirit of Lavender.

“Take of Spirit of Lavender *three pints*; Spirit of Rosemary *a pint*; Cinnamon, bruised, *an ounce*; Cloves, bruised, *two drachms*; Nutmeg, bruised, *half an ounce*; Red Saunders, rasped, *three drachms*. Macerate for fourteen days, and filter through paper.” *U. S.*

The *London College* takes *a pint and a half* [Imperial measure] of spirit of lavender, *half a pint* [Imp. meas.] of spirit of rosemary, *two drachms and a half* of bruised cinnamon, *the same quantity* of bruised nutmegs, and *five drachms* of sliced red saunders; and proceeds as above. The *Edinburgh College* takes *two pints* [Imp. meas.] of spirit of lavender, *twelve fluidounces* of spirit of rosemary, *an ounce* of cinnamon in coarse powder, *two drachms* of bruised cloves, *half an ounce* of bruised nutmeg, and *three drachms* of red saunders; macerates for seven days, and then strains the liquor through calico. The *Dublin College* orders *half an ounce* only of cinnamon, and *an ounce* of red saunders, and digests for ten days; but in other respects conforms with the directions of the *U. S. Pharmacopœia*.

This is a delightful compound of spices, much employed as an adjuvant and corrigent of other medicines, and as a remedy for gastric uneasiness, nausea, flatulence, and general languor or faintness. The dose is from thirty drops to a fluidrachm, and is most conveniently administered on a lump of sugar.

Off. Prep. Aqua Laurocerasi, *Ed.*; Liquor Potassæ Arsenitis, *U. S.*, *Lond.*, *Ed.* W.

SPIRITUS MENTHÆ PIPERITÆ. *Lond.*, *Dub.* **SPIRITUS MENTHÆ.** *Ed.* *Spirit of Peppermint.*

"Take of Oil of Peppermint *three drachms*; Proof Spirit *a gallon* [Imperial measure]; Water *a pint* [Imperial measure]. Mix them; then with a slow fire distil a gallon." *Lond.*

The *Edinburgh College* prepares this spirit from *one pound and a half* of fresh peppermint, in the same manner as spirit of caraway. (See *Spiritus Carui*.)

"Take of Oil of Peppermint, by weight, *half an ounce*; Rectified Spirit *a gallon*. Add the Spirit to the Oil, and pour on them as much water as will prevent empyreuma, after distillation; then by a gentle fire, distil a gallon." *Dub.*

The spirit of peppermint has no advantage over a simple solution of the oil in alcohol. Such a solution is usually kept in the shops, under the name of *essence of peppermint*, and was adopted among the officinal preparations, at the last revision of the *U. S. Pharmacopœia*, with the title of *tincture of oil of peppermint*. (See *Tinctura Olei Menthæ Piperitæ*.) W.

SPIRITUS MENTHÆ PULEGII. *Lond.*, *Dub.* *Spirit of European Pennyroyal.*

This is prepared by the *London College* from the oil of European pennyroyal, in the manner directed by the same College for the preparation of spirit of peppermint. The *Dublin College* prepares it by distilling together *six scruples* of the oil and *a gallon* of proof spirit. It is never used in this country. W.

SPIRITUS MENTHÆ VIRIDIS. *Lond.*, *Dub.* *Spirit of Spearmint.*

This is prepared by the *London* and *Dublin Colleges* from the oil of spearmint, in the manner directed by the two Colleges respectively for the preparation of the spirit of peppermint.

The two spirits are used for the same purposes, in the dose of from thirty drops to a fluidrachm. W.

SPIRITUS MYRISTICÆ. *U. S.*, *Lond.*, *Ed.* **SPIRITUS NUCIS MOSCHATÆ.** *Dub.* *Spirit of Nutmeg.*

"Take of Nutmeg, bruised, *two ounces*; Diluted Alcohol *a gallon*; Water *a pint*. Mix them, and with a slow fire distil a gallon." *U. S.*

The *London* and *Edinburgh Colleges* take *two ounces and a half* of bruised nutmegs, *a gallon* [Imperial measure] of proof spirit, and *a pint* [Imp. meas.] of water; mix them; and distil a gallon. The *Dublin College* macerates together for twenty-four hours *two ounces* of bruised nutmeg, *a gallon* of proof spirit, and enough water to prevent empyreuma, and then distils a gallon.

The spirit of nutmeg is used chiefly for its flavour, as an addition to other medicines. The dose is one or two fluidrachms.

Off. Prep. Mistura Ferri Composita, *Lond.*, *Ed.*

W:

SPIRITUS PIMENTÆ. *U. S.*, *Lond.*, *Ed.*, *Dub.* *Spirit of Pimento.*

"Take of Pimento, bruised, *two ounces*; Diluted Alcohol *a gallon*; Water *a pint*. Macerate the Pimento in the Diluted Alcohol for twenty-four hours; then add the Water, and with a slow fire distil a gallon." *U. S.*

The *London College* orders it to be prepared in the same manner as

spirit of nutmeg; the *Edinburgh*, from *half a pound* of bruised pimento, in the same manner as spirit of caraway. The *Dublin* macerates together for twenty-four hours *three ounces* of bruised pimento, *a gallon* of proof spirit, and sufficient water to prevent empyreuma, and then distils a gallon.

This preparation may be used for the general purposes of the aromatic spirits, in the dose of one or two fluidrachms. W.

SPIRITUS ROSMARINI. *U. S., Lond., Ed.* SPIRITUS RORIS-MARINI. *Dub.* *Spirit of Rosemary.*

“Take of Oil of Rosemary [by weight] *two drachms*; Alcohol *a gallon*; Water *a pint*. Mix them, and with a slow fire distil a gallon.” *U. S.*

The *London College* takes *two drachms* of oil of rosemary, *a gallon* [Imperial measure] of rectified spirit, and *a pint* [Imp. meas.] of water; mixes them; and then, with a slow fire, distils a gallon. The *Edinburgh College* takes *two pounds and a half* of rosemary, and proceeds as for the spirit of lavender. The *Dublin College* employs *a pound and a half* of the fresh tops and *a gallon* of proof spirit, and distils five pounds with a moderate heat. This College also prepares the spirit by distilling together *six scruples* of the oil, and *a gallon* of proof spirit.

Spirit of rosemary is a grateful perfume, and is used chiefly as an ingredient in lotions or liniments.

SPONGIA.

Preparation of Sponge.

SPONGIA USTA. *U. S.* PULVIS SPONGIAE USTAE. *Dub.* *Burnt Sponge.*

“Take of Sponge *a convenient quantity*. Cut it into pieces, and beat it, that any extraneous matters may be separated; then burn it in a close iron vessel until it becomes black and friable; lastly, rub it into very fine powder.” *U. S.*

The *Dublin* process does not materially differ from the above.

The sponge is decomposed, the volatile matters being driven off by the heat, and a black friable coal remaining. Preuss found that, of 1000 parts of sponge submitted to calcination, 343·848 were dissipated; and the residue consisted of 327·0 parts of carbon and insoluble matters, 112·08 of chloride of sodium, 16·43 of sulphate of lime, 21·422 of iodide of sodium, 7·57 of bromide of magnesium, 103·2 of carbonate of lime, 35·0 of phosphate of lime, 4·73 of magnesia, and 28·72 of protoxide of iron. (*Pharm. Central-Blatt*, 1837, 169.) Herberger found in burnt sponge one per cent. of iodide of potassium, and 0·5 per cent. of bromide of potassium. (*Annalen der Pharm.* xx. 204.) As the remediate value of burnt sponge depends chiefly upon the presence of iodine, it cannot be esteemed good unless it afford purple fumes when acted on by sulphuric acid assisted by heat. It is said that the preparation is most efficient as a remedy when the sponge is kept on the fire no longer than is necessary to render it friable. The powder is then of a much lighter colour. Guibourt recommends that the sponge selected for burning should be unwashed, of a strong odour, firm, and compact, that it should be put into a roaster similar to that sometimes used for coffee, and heated over a moderate fire till it becomes of a blackish-brown colour, that it should then be removed, powdered, and enclosed in a well-stopped glass

bottle. It is best when recently prepared; as the iodine is dissipated by time, and the specimens at first richest in this principle, contain little of it at the end of a year. (*Journ. de Chim. Med.*, Dec. 1831.) According to Herberger, the fine and coarse sponges do not materially differ in the proportion of their inorganic constituents; so that the coarse may be selected for this operation.

Burnt sponge has been highly recommended in goitre, glandular swellings of a scrofulous character, and obstinate cutaneous eruptions. It is most conveniently administered mixed with syrup or honey, in the form of an electuary, with the addition of some aromatic, as powdered cinnamon. The dose is from one to three drachms. W.

STANNUM.

Preparation of Tin.

PULVIS STANNI. U. S. STANNI PULVIS. *Ed., Dub.* Powder of Tin.

“Take of Tin a convenient quantity. Melt it in an iron vessel over the fire, and, while it is cooling, stir it until it is reduced to a powder, which is to be passed through a sieve.” *U. S.*

“Melt Tin in an iron vessel; pour it into an earthenware mortar, heated a little above the melting point of the metal; triturate briskly as the metal cools, ceasing as soon as a considerable proportion is pulverized; sift the product, and repeat the process with what remains in the sieve.” *Ed.*

“Take of very pure Tin any quantity. Having melted it over the fire, agitate it strongly while congealing, so that it may be converted into a powder, which, when cold, is to be passed through a sieve.” *Dub.*

Tin, being a very fusible metal, is easily granulated by fusion and subsequent agitation when in the act of congealing. The process is most conveniently performed, on a small scale, in a wooden box, the inside of which has been well rubbed with chalk. This may be afterwards washed away by water; and, as the granulated powder is of unequal degrees of fineness, the coarser particles must be separated by a sieve. For the properties and tests of purity of this metal see *Stannum*.

Medical Properties and Uses. Powder of tin is used exclusively as an anthelmintic, and is supposed to act by its mechanical properties. It is considered particularly adapted to the expulsion of the *Ascaris lumbricoides*, and is sometimes employed to expel the tape worm, though for this purpose, oil of turpentine is more efficacious. For internal exhibition it should be free from oxidation. The dose is half an ounce, mixed with molasses, given for several successive mornings, and then followed by a brisk cathartic. Dr. Alston was in the habit of giving larger doses for the expulsion of the tape worm. He began by giving an ounce on an empty stomach, which was followed, for two successive days, by half an ounce each day, and finally by a brisk purge. B.

STRYCHNIA.

Strychnia.

STRYCHNIA. U. S., Lond., *Ed.* *Strychnia.*

“Take of Nux Vomica, rasped, four pounds; Lime, in powder, six ounces; Muriatic Acid three fluidounces; Alcohol, Diluted Sulphuric Acid, Solution of Ammonia, Purified Animal Charcoal, Water, each, a sufficient

quantity. Digest the Nux Vomica in two gallons of Water, acidulated with a fluidounce of the Muriatic Acid, for twenty-four hours; then boil for two hours, and strain with expression through a strong linen bag. Boil the residuum twice successively in the same quantity of acidulated Water, each time straining as before. Mix the decoctions and evaporate to the consistence of thin syrup; then add the Lime previously mixed with a pint of Water, and boil for ten minutes, frequently stirring. Pour the mixture into a double linen bag, and, having washed the precipitate well with water, press, dry, and powder it. Treat the powder repeatedly with boiling Alcohol, until deprived of its bitterness; mix the liquors; and distil off the Alcohol by means of a water-bath. Mix the residue with Water, and, having applied heat, drop in sufficient Diluted Sulphuric Acid to neutralize and dissolve the Strychnia; then add Purified Animal Charcoal, boil for a few minutes, filter, evaporate, and crystallize. Dissolve the crystals in Water, and add sufficient Solution of Ammonia to precipitate the Strychnia. Lastly, dry the precipitate on bibulous paper." *U. S.*

"Take of Nux Vomica, bruised, *two pounds*; Rectified Spirit *three gallons* [Imperial measure]; Diluted Sulphuric Acid, Magnesia, Solution of Ammonia, each, *a sufficient quantity*. Boil the Nux Vomica with a gallon of the Spirit, for an hour, in a retort, with a receiver fitted to it. Pour off the liquor, and boil the residue again, and a third time, with another gallon of the Spirit, and with the Spirit recently distilled, and pour off the liquor. Press the Nux Vomica, and, having mixed and filtered the liquors, distil the Spirit. Evaporate the residue to the proper consistence of an extract. Dissolve this in cold water and filter. Evaporate the solution, with a gentle heat, to the consistence of syrup. To this, while yet warm, gradually add the Magnesia to saturation, shaking them together. Set aside for two days, and then pour off the supernatant liquor. Press what remains wrapped in a linen cloth. Boil it in Spirit, then filter, and distil the spirit. Add to what remains a very little Diluted Sulphuric Acid mixed with water, and macerate with a gentle heat. Set it aside for twenty-four hours that crystals may form. Press these and dissolve them. To their solution in water add Ammonia, occasionally shaking, that the Strychnia may be thrown down. Lastly, dissolve this in boiling Spirit, and set it aside that pure crystals may form." *London.*

"Take of Nux Vomica *one pound*; Quicklime *one ounce and a half*; Rectified Spirit *a sufficiency*. Subject the Nux Vomica for two hours to the vapour of steam, chop or slice it, dry it thoroughly in the vapour-bath, or hot air-press, and immediately grind it in a coffee-mill. Macerate it for twelve hours in two pints [Imperial measure] of water and boil it; strain through linen or calico, and squeeze the residuum; repeat the maceration and decoction twice with a pint and a half of water. Concentrate the decoctions to the consistence of thin syrup; add the Lime in the form of milk of lime; dry the precipitate in the vapour-bath; pulverize it, and boil it with successive portions of Rectified Spirit till the Spirit cease to acquire a bitter taste. Distil off the spirit till the residuum be sufficiently concentrated to crystallize on cooling. Purify the crystals by repeated crystallizations." *Ed.*

It should be recollected that the British Imperial measure is employed by the London and Edinburgh Colleges throughout these processes.

In preparing strychnia, the first step is properly to comminute the nux vomica. This may be done by rasping the seeds, or, as directed in the Edinburgh Pharmacopœia, by first softening them by steam, then slicing, drying, and grinding them. The next object is to extract the strychnia. For this purpose water acidulated with muriatic acid is employed in the

U. S. process, alcohol in the London, and water alone in the Edinburgh. In the two latter, the native igasurate of strychnia is taken up, in the first, the muriate, which is a very soluble salt. The menstruum of the U. S. Pharmacopœia is less costly than the London, and probably more effective than the Edinburgh. Besides, when alcohol is used, it is necessary to evaporate the tincture, and then treat the extract with water, in order to get an aqueous solution of the alkali. The salt of strychnia existing in the solution is next decomposed either by lime, as in the U. S. and Edinburgh processes, or by magnesia, as in the London. The alkaline base is precipitated along with the excess of lime or magnesia and impurities. The strychnia is extracted from the precipitate by boiling alcohol, and may be obtained in crystals by the concentration of the solution. But in this state it is much coloured and impure. The Edinburgh College contents itself with directing it to be purified by repeated solutions and crystallizations. In the two other processes, the impure strychnia is converted into a sulphate by the addition of sulphuric acid, and precipitated again by ammonia; being, while in the state of the sulphate, decolorized, according to the directions of the U. S. Pharmacopœia, by means of animal charcoal. The London College proceeds one step further, and obtains the alkali in crystals by dissolving the precipitated powder in boiling alcohol, and setting the solution aside to crystallize. Throughout the process, the brucia contained in the nux vomica attends the strychnia, and is only left behind in the mother liquors, when the latter alkali crystallizes from the alcoholic solution upon cooling; brucia being much more soluble than strychnia in cold alcohol. It would, therefore, be better to conclude the U. S. process by one or more solutions and crystallizations in alcohol, as directed by the London and Edinburgh Colleges. With this addition, we should give the preference to our own officinal process. To free the strychnia entirely from brucia requires repeated crystallizations, and a little of the latter principle is consequently almost always retained; but the impurity is not injurious; as the effects of the two alkalies upon the system are very similar. The bean of St. Ignatius yields strychnia more easily and more largely than nux vomica; but is less plentiful.

If thought desirable, brucia may be in great measure separated from the strychnia of the shops, by dissolving the latter in nitric acid, very much diluted, filtering, and concentrating to the point of crystallization. The nitrate of brucia crystallizes in short, thick, dense prisms, grouped together; the nitrate of strychnia in radiated tufts of long, light, capillary needles. By gentle agitation with water, the latter salt is suspended and may be poured off, leaving the former. The alkalies may be obtained by dissolving the salts separately in water, and precipitating with ammonia. (*Christison's Dispensatory.*)

As usually kept in the shops, strychnia is a grayish-white powder. When rapidly crystallized from its alcoholic solution, it has the form of a white, granular powder; when slowly crystallized, that of elongated octohedra, or quadrilateral prisms with quadrilateral terminations. It is permanent in the air, inodorous, but excessively bitter, with a metallic after taste. So intense is its bitterness, that one part of strychnia is said to communicate a sensible taste to 600,000 parts of water. It melts like a resin, but is not volatile, being decomposed at a comparatively low temperature. It is soluble in 6667 parts of water at 50°, and about 2000 parts at the boiling point. Boiling officinal alcohol dissolves it without difficulty, and deposits it upon cooling. In absolute alcohol and in ether it is very sparingly soluble. The volatile oils dissolve it freely. It has an alkaline reaction on test paper, and forms salts with the

acids. Nitric acid does not redden it if perfectly pure, but almost always reddens it as found in the shops, in consequence of the presence of brucia. It consists of carbon, hydrogen, oxygen, and nitrogen; but the proportion of its constituents is very differently given by different authors. In the edition of Turner's Chemistry by Liebig and Gregory, the composition is stated to be $C_{44}H_{28}O_4N_2$. The salts of strychnia are for the most part soluble and crystallizable. Their solution is decomposed by the alkalies and their carbonates, and by tannic, but not by gallic acid; and is not affected by the sesquisalts of iron. Strychnia is apt to contain impurities, of which the chief, besides brucia, are colouring matter and lime or magnesia. The Edinburgh College gives the following test of its purity. "A solution of 10 grains in 4 fluidrachms of water by means of a fluidrachm of pyroligneous acid, when decomposed by one fluidounce of concentrated solution of carbonate of soda, yields on brisk agitation a coherent mass, weighing when dry 10 grains, and entirely soluble in solution of oxalic acid."

Medical Properties and Uses, &c. The effects of strychnia upon the system are identical in character with those of nux vomica, and it is employed for the same purposes as a medicine. (See *Nux Vomica*, page 478.) It operates in the same way by whatever avenue it may enter into the circulation; but is said to act most powerfully when injected into the veins or applied to a fresh wound. The blood of an animal under its influence produces similar effects in another if transfused into its veins. In over doses it is a most violent poison. Pelletier and Caventou killed a dog in half a minute with one-sixth of a grain of the pure alkali. One grain or even less might prove fatal in the human subject. Different persons are very differently susceptible to its action, and some are powerfully affected by the smallest doses. Besides, being more or less impure as kept in the shops, it cannot be relied on with certainty. Hence the necessity of great caution in prescribing it, and of carefully watching the patient during its use. The best plan is always to begin with very small doses, and gradually increase till its effects are observed. From one-twelfth to one-sixth of a grain internally, and from a quarter to half a grain externally upon a blistered surface, may be employed at first; but, if the alkali is very pure, the dose may be still further reduced with propriety. It is most conveniently given in the form of pill. It may be given also dissolved in water acidulated with sulphuric, muriatic, nitric, or acetic acid. In this form it is in saline combination; but the effects of its salts are the same as those of the pure alkali. W.

STYRAX.

Preparation of Storax.

STYRAX PURIFICATA. U.S. STYRAX COLATUS. Lond. EXTRACTUM STYRACIS. Ed. *Purified Storax.*

"Take of Storax, Alcohol, each, *a sufficient quantity*. Dissolve the Storax in the Alcohol, and strain the solution; then distil off the alcohol with a gentle heat, until the Storax acquires the proper consistence." U. S.

The purification of storax is directed by the *London College*, in a similar manner, under the head of the gum-resins.

"Take *any convenient quantity* of Storax, in fine powder. Exhaust it by boiling it in successive quantities of Rectified Spirit; filter the spirituous solutions; distil off the greater part of the spirit; evaporate the remainder over the vapour-bath to the consistence of a thin extract." Ed.

Storax, as found in the shops, is usually so much adulterated as to render its purification necessary, before it can be applied to the purposes for which it is officinally directed. As it is wholly soluble in alcohol, and little of its active matter is driven off at the boiling point of that fluid, there can be no chemical objection to the above process. Another method, sometimes followed, is to express between heated iron plates the balsam from the foreign matters with which it is associated; but if the process be not very carefully conducted, the heat employed to melt the storax will be sufficient to dissipate a portion of the benzoic acid, which is one of its essential ingredients.

Off. Prep. Pilulæ Styracis Compositæ, *Lond., Ed., Dub.*; Tinctura Benzoini Composita, *U. S., Lond., Dub.* W.

SULPHUR.

Preparations of Sulphur.

SULPHUR PRÆCIPITATUM. *U. S.* LAC SULPHURIS. *Pre-
cipitated Sulphur. Milk of Sulphur.*

“Take of Sulphur [sublimed] *a pound*; Lime *a pound and a half*; Water *two gallons*; Muriatic Acid *a sufficient quantity*. Slake the Lime with a small portion of the Water, and, having mixed it with the Sulphur, add the remainder of the Water, boil for two or three hours, occasionally adding water so as to preserve the measure, and filter. Dilute the filtered liquor with an equal bulk of water; then drop into it sufficient Muriatic Acid to precipitate the Sulphur. Lastly, wash the precipitate repeatedly with water till the washings are tasteless, and dry it.” *U. S.*

In this process two eqs. of lime react with six of sulphur, so as to form two eqs. of bisulphuret of calcium, and one of hyposulphurous acid, which latter then unites with one eq. of lime to form hyposulphite of lime. On the addition of the muriatic acid, six eqs. of sulphur are precipitated (four from the bisulphuret of calcium and two from the hyposulphurous acid), and the calcium and oxygen unite with the muriatic acid, so as to form chloride of calcium and water. This acid is the most eligible precipitant for the sulphur, as it gives rise to chloride of calcium, which is a very soluble salt, and easily washed away. Sulphuric acid is altogether inadmissible for the purpose; as it generates sulphate of lime, which, from its sparing solubility, becomes necessarily intermingled with the sulphur.

Properties, &c. Precipitated sulphur is in white friable lumps of a pale yellowish-green tint, consisting of finely divided particles, slightly cohering together, and, when recently prepared, devoid of taste, but possessing a peculiar smell. When long exposed, in a moist state, to the air, it becomes strongly contaminated with sulphuric acid. (*Annalen der Pharm.* xx. 151.) From its colour it was formerly called *lac sulphuris*, or *milk of sulphur*. It is insoluble in water, but dissolves in a boiling solution of caustic potassa. When of a brilliant white colour, the presence of sulphate of lime may be suspected, in which case the sulphur will not be wholly volatilized by heat. When pure it communicates a harsh feel when rubbed between the fingers, owing to the friction between the crystalline particles. (*Dr. Bridges.*) We have seen a sample of so-called precipitated sulphur, which consisted almost entirely of sulphate of lime. It differs from sublimed sulphur, in being in a state of more minute division, and in presenting, after fusion, a softer and less brittle mass. Its peculiarities are supposed to depend upon a portion of water, which, however, is present in too small a quantity to constitute a

regular *hydrate*. According to Rose, its white colour depends upon the presence of a small proportion of bisulphuretted hydrogen.

Medical Properties and Uses. Precipitated sulphur possesses the same medical properties with sublimed sulphur, but is preferred by some practitioners on account of its freedom from colour. Its state of extreme division renders it more readily suspended in liquids than sublimed sulphur; but its liability to become acid by keeping is an objection to it. It is sometimes selected for forming ointments, which have the advantage of appearance, in being of a lighter colour than when made of sublimed sulphur. The dose is from two to three drachms. (See *Sulphur*.) B.

SULPHURIS IODIDUM. U. S. *Iodide of Sulphur.*

“Take of Iodine *four ounces*; Sulphur *an ounce*. Rub the Iodine and Sulphur together in a glass, porcelain, or marble mortar until they are thoroughly mixed. Put the mixture into a matrass, close the orifice loosely, and apply a gentle heat so as to darken the mass without melting it. When the colour has become uniformly dark throughout, increase the heat so as to melt the Iodide; then incline the matrass in different directions, in order to return into the mass any portions of Iodine which may have condensed on the inner surface of the vessel; lastly, allow the matrass to cool, break it, and put the Iodide into bottles, which are to be well stopped.” U. S.

The above process is that of the French Codex. The combination may be conveniently effected in a Florence flask. The resulting iodide has a grayish-black colour, and radiated crystalline appearance like sulphuret of antimony. Its smell resembles that of iodine, and it stains the cuticle in a similar manner. It is entirely volatilized by heat, and when boiled with water is decomposed, iodine escaping with the steam, and sulphur being deposited nearly pure. It has not been analyzed, but is probably a bisulphuret. Iodide of sulphur has been used by Biett, Rayer, Lugol, and others, as an external application in various skin diseases, such as *tinea capitis*, *lupus*, *lepra*, &c. It is applied in the form of ointment, made by mixing from ten to thirty grains of the iodide with an ounce of lard. Of this a drachm may be used at each friction. B.

SYRUPI.

Syrups.

Syrups are concentrated solutions of sugar in watery fluids, either with or without medicinal impregnation. When the solution is made with pure water, it is named *syrup* or *simple syrup*, when with water charged with one or more medicinal agents, it is called in general terms a *medicated syrup*, and receives its particular designation from the substance or substances added.

Medicated syrups are prepared by incorporating sugar with vegetable infusions, decoctions, expressed juices, fermented liquors, or simple aqueous solutions. When the active matter of the vegetable is not readily soluble in water, or is volatilized or decomposed by a heat of 212° , it is sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off. Medicated syrups are also occasionally prepared by adding a tincture to simple syrup and evaporating the alcohol. Since the introduction of the process of filtration by displacement into use, it has been applied very advantageously to the preparation of various syrups, especially of those made from vegetables of which the active principle is injured or

dissipated by decoction. But, unless the operator be at once skilful and very careful, there will be great danger of imperfectly extracting the active matters, and thus making a feeble preparation. For the mode of properly conducting this process the reader is referred to pages 763 and 769.

The quality and quantity of the sugar employed are points of importance. Refined sugar should always be preferred, as it often saves the necessity of clarification, and makes a clearer and better flavoured syrup than the impure kinds. The U.S. Pharmacopœia simply directs sugar, but explains that it is the purified or refined sugar which is indicated by that term. In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur, if too abundant, crystallization. The proper proportion is about two parts to one of the liquid. A somewhat smaller quantity will answer where acids, such as lemon juice or vinegar, are used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary to evaporate a large proportion of the watery fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case, care is requisite not to apply a heat too great or too long continued, lest the active principles should be injured. When these are very volatile or easily decomposed by heat, it is necessary to dispense with concentration altogether. Some substances which are volatilized or decomposed at the temperature of boiling water, remain fixed and unaltered at that which is necessary for the evaporation of alcohol. These, as before observed, may be dissolved in diluted alcohol, and the concentration effected by evaporating the spirituous part of the solvent. Independently of the injury which the medicinal ingredient of the syrup may sustain, the syrup itself is apt to become brown by a long continued application of heat, even when the degree is not excessive. It is recommended, therefore, that syrups which admit of concentration, should be boiled briskly over a lively fire, so as to accomplish the object as quickly as possible. It is important to be able to ascertain positively when they have attained the due consistence. An operator skilled in their preparation can judge with sufficient accuracy by various familiar signs;—such as the slowness with which the parts of a drop of syrup coalesce when previously separated by the edge of a blunt instrument; and the receding of the last portion of each drop, when the syrup, after being cooled, is poured out drop by drop. A pellicle forming upon the surface of the syrup when it cools, indicates that it has been too much boiled. But these signs are not to be relied on except by those who have acquired much experience. The easiest method of ascertaining the proper point of concentration is by the use of Baumé's hydrometer. This should stand at 30° in boiling syrup (30½ in hot weather), and at 35° in the syrup when it is cool. Another very accurate though less ready method is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup when boiling should have a sp. gr. of about 1.261—when cold, about 1.319. Thomson and Duncan are mistaken in giving the proper sp. gr. of cold syrup as 1.385. We found that of a specimen of simple syrup made with two pounds and a half of sugar to a pint of water, to be 1.326 at 68° F.; and this consistence is rather too great for practical convenience in cold weather. A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 221° F. This indication is founded on the fact, that the boiling point of syrup rises in proportion to the increase of its density.

When carefully prepared with double refined sugar, syrups generally

require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. Should they, however, want the due degree of clearness, they may be filtered through flannel, or, when not likely to be injured by the treatment, may be clarified by means of the white of eggs or animal charcoal, as mentioned under the head of *Syrupus*.

The medicated syrups are liable to undergo various alterations according to their nature and mode of preparation. The acid syrups, when too much boiled, often let fall a copious white precipitate, which is said to be a saccharine matter analogous to the sugar of grapes, produced by the reaction of the acid upon the sugar. It has been shown that, even at ordinary temperatures, acids slowly convert common sugar into the sugar of grapes, which being less soluble than the former, is gradually deposited in the form of crystalline grains. Syrups which contain too little sugar are apt to pass into the vinous fermentation, in consequence of the presence of matters which act as a ferment. Those which contain too much, deposit a portion in the crystalline state, and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of a due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups, enclosed, while they are still hot, in bottles, are apt to ferment; because the watery vapour, rising to the surface and there condensing, diminishes the proportion of sugar, so as to produce a commencement of chemical action, which gradually extends through the whole mass. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbonic acid, and acquire a vinous odour from the presence of alcohol; while their consistence is diminished by the loss of a portion of the sugar which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases or goes on more slowly, owing to the preservative influence of that principle; and, as the active ingredient of the syrup has frequently undergone no material change, the preparation may often be recovered by boiling so as to drive off the alcohol and carbonic acid, and concentrate the liquid sufficiently. A syrup thus revived is less liable afterwards to undergo change, because the principles which acted as ferments have been diminished or consumed. It is obvious that syrups which depend for their virtues upon a volatile ingredient, or one readily changeable by heat, cannot be restored to their original condition.

At best, syrups are too apt to change, and various measures have been proposed for their preservation. According to Dr. Macculloch, the addition of a little sulphate of potassa, or of chlorate of potassa, which is tasteless, prevents their fermentation. M. Chereau has found sugar of milk effectual to the same end, in the instance of the syrup of poppies; and it may prove useful in others. The proportion which he employs is 32 parts of the sugar of milk to 1000 of the syrup. Mr. E. Durand has found that 1.3 per cent. of Hoffmann's anodyne (*Spiritus Ætheris Sulphurici Compositus*), added to syrups, has the property of completely arresting or preventing fermentation, probably through the agency chiefly of the oil of wine which it contains. (*Am. Journ. of Pharm.* xiii. 185.) But the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stopped, which should be put in the cellar or other cool place.

The following general officinal directions are given in relation to syrups.

"Syrups whose density is not precisely determined by the process, should have the specific gravity 1·261 when boiling, and about 1·319 at ordinary temperatures." *U. S.*

"Let the syrups be preserved in a place where the heat never exceeds 55°." *Lond.* It would be difficult to comply exactly with such a rule in this country.

"When no mention is made of the weight of sugar or the mode of dissolving it, syrups are to be prepared according to the following rule. Take of Refined Sugar, in fine powder, *twenty-nine ounces*; of the Liquor prescribed *a pint*. Add the Sugar by degrees, and digest it with a medium heat [from 100° to 200° F.] in a covered vessel, frequently shaking, till it is dissolved; then set aside the solution for twenty-four hours; remove the scum, and pour off the syrup from the dregs if there be any." *Dub.* *W.*

SYRUPUS. *U. S., Lond.* SYRUPUS SIMPLEX. *Ed., Dub.* *Syrup. Simple Syrup.*

"Take of Sugar [refined] *two pounds and a half*; Water *a pint*. Dissolve the Sugar in the Water with the aid of heat, remove any scum which may form, and strain the solution while hot." *U. S.*

"Take of Sugar [refined] *ten pounds*; Water *three pints* [Imperial measure]. Dissolve the Sugar in the Water with a gentle heat." *Lond.*

"Take of Pure Sugar *ten pounds*; boiling Water *three pints* [Imperial measure]. Dissolve the Sugar in the Water with the aid of a gentle heat." *Ed.*

"Take of Refined Sugar, finely powdered, *twenty-nine ounces*; Water *a pint*. Add the Sugar gradually to the Water, and digest it with a medium heat [from 100° to 200° F.] in a close vessel till it is dissolved, frequently stirring; afterwards pour off from the dregs if there be any." *Dub.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavour, thick, viscid, nearly colourless, and perfectly transparent. If somewhat turbid, as it is apt to be when made with sugar not well refined, it may be clarified by beating the white of an egg to a froth with three or four ounces of water, mixing this with the syrup, boiling the mixture for a short time that the albumen may coagulate, and taking off the scum which rises to the surface, or separating it by filtration through paper or flannel. Two gallons of the syrup may be thus clarified. Any colour and peculiar flavour which it may possess, may be removed by treating it, at the same time, with a small proportion (about 5 per cent.) of animal charcoal.

The white of egg is beaten to a froth in order that, when it coagulates, it may be rendered by the air which it contains specifically lighter than the syrup, and thus rise to the surface. If not thus treated, it floats when coagulated in the syrup, or sinks to the bottom. Now it is obvious that, if the syrup and albumen be heated together, the latter must be deprived of a portion of the air which it contains, before the point of coagulation is attained, and thus be rendered less disposed to rise to the surface. Guibourt, therefore, recommends that the albumen should not be added till the syrup is boiling hot, and should then be poured into it from a height in order to increase the quantity of air entangled in it.

M. Salles, an apothecary of Clermond-Ferrand, in France, recommends that syrups which require clarification should be treated in the following manner. Allow the liquor with which the syrup is to be prepared, without previously decanting or filtering it, to become quite cold; then, mix with it

the white of eggs unbeaten, in the proportion of one egg for every five or six pounds (avoirdupois) of sugar employed; and, having added the sugar or honey, boil the whole for half an hour, or until a portion of the syrup upon cooling exhibits flocculi of albumen floating in a transparent medium. During the ebullition care must be taken to agitate the syrup in such a manner as to prevent the formation of foam upon its surface. When allowed to cool, the coagulated albumen with impurities subsides, and the clear syrup floats above, and may be drawn off or decanted. In this process the albumen sinks because not incorporated with air. M. Salles calls it clarification *per descensum*, and states that it is applicable to all syrups of a density below 30° Baumé at the boiling point. (*Journ. de Pharm.* xxiv. 490.)

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

Off. Prep. Confectio Opii, *Lond., Dub.*; Infusum Catechu, *Ed.*; Syrupus Rhei Aromaticus, *U. S.*; Syrupus Tolutani, *U. S., Ed., Dub.*; Syrupus Zingiberis, *U. S.* W.

SYRUPUS ACETI. *Ed.* Syrup of Vinegar.

"Take of Vinegar, French in preference, *eleven fluidounces*; Pure Sugar *fourteen ounces*. Boil them together." *Ed.*

Syrup of vinegar forms with water a refrigerant and grateful drink in febrile complaints. It may be added to barley water and other farinaceous and mucilaginous beverages and mixtures, when a vegetable acid is not contra-indicated. W.

SYRUPUS ALLII. *U. S.* Syrup of Garlic.

"Take of fresh Garlic, sliced, *six ounces*; Distilled Vinegar *a pint*; Sugar [refined] *two pounds*. Macerate the Garlic in the Vinegar, in a glass vessel, for four days; then express the liquor, and set it by that the dregs may subside; lastly, add the Sugar to the clear liquor, and proceed in the manner directed for Syrup." *U. S.*

This preparation is made upon correct principles, as vinegar is a much better solvent of the active matter of garlic than water. In the last edition of the *U. S. Pharmacopœia*, the proportion of garlic has been judiciously increased to three times its former amount. The syrup is given in chronic catarrhal affections of the lungs, and is particularly beneficial in infantile cases, by the stimulus which it affords to the nervous system. A teaspoonful may be given for a dose to a child a year old. W.

SYRUPUS ALTHÆÆ. *Lond., Ed., Dub.* Syrup of Marsh-mallow.

"Take of Marshmallow Root, bruised, *eight ounces*; Sugar [refined] *two pounds and a half*; Water *four pints* [Imperial measure]. Boil down the Water with the Root to one-half, and express the liquor when cool. Set it by for twenty-four hours that the dregs may subside; then pour off the liquor, and having added the Sugar, boil down to the proper consistence." *Lond.*

The *Edinburgh* process corresponds with the above, except that it closes with dissolving the sugar with the aid of heat, without boiling down the syrup.

The *Dublin College* takes *half a pound* of the fresh root, *two pounds* of refined sugar, and *four pints* of water, and proceeds in the same manner as the *London College*.

This syrup contains a considerable quantity of starch, besides mucilage, and is very liable to ferment. The French prepare it with cold water, and thus avoid the starch. It is simply demulcent; but is inferior to the mucilage of gum Arabic, and in this country is very seldom prepared. W.

SYRUPUS AMYGDALÆ. U.S. *Syrup of Almonds. Syrup of Orgeat.*

“Take of Sweet Almonds *a pound*; Bitter Almonds *four ounces*; Water *three pints*; Sugar *six pounds*. Having blanched the Almonds, rub them in a mortar to a very fine paste, adding, during the trituration, three fluid-ounces of the Water and a pound of the Sugar. Mix the paste thoroughly with the remainder of the Water, strain with strong expression, add the remainder of the Sugar to the strained liquor, and dissolve it with the aid of a gentle heat. Strain the Syrup through fine linen, and having allowed it to cool, put it into bottles, which must be well stopped, and kept in a cool place.” U. S.

This process corresponds closely with that of the French Codex. Orange-flower water, however, which is an ingredient of the French preparation, is wanting in ours. It may be added to the syrup in the quantity of half a pint immediately after the sugar has dissolved.

This is an elegant syrup, much employed in Europe, and occasionally in this country. It is demulcent, nutritive, and, in consequence of the hydrocyanic acid of the bitter almonds, somewhat sedative. It may be added to cough mixtures, or used for flavouring drinks administered in complaints of the chest. W.

SYRUPUS AURANTII CORTICIS. U.S. SYRUPUS AURANTII. *Lond., Ed., Dub. Syrup of Orange Peel.*

“Take of Orange Peel, bruised, *two ounces*; boiling Water *a pint*; Sugar [refined] *two pounds and a half*. Macerate the Orange Peel in the Water, in a covered vessel, for twelve hours, and strain; then add the Sugar, and proceed in the manner directed for Syrup.” U. S.

The British Colleges direct the fresh peel of Seville oranges. The *London College* takes *two ounces and a half* of the fresh peel, *a pint* [Imperial measure] of boiling water, and *three pounds* of refined sugar; macerates the peel in the water for twelve hours, in a lightly-covered vessel; then pours off the liquor, and adds the sugar to it. The *Edinburgh College* takes the same materials in the same quantities; infuses the peel in the water for twelve hours in a covered vessel, pours off the liquor, filters if necessary, adds the sugar, and dissolves it with the aid of heat. The *Dublin College* employs *eight ounces* of the peel, *six pints* of boiling water, and the quantity of sugar in its general directions (page 1145); and dissolves the sugar without heat.

In the preparation of this syrup, the solution of the sugar in the infusion of orange peel should be effected with as little heat as possible, in consequence of the volatile nature of the active principle of the peel; and, to facilitate the solution, the sugar should be previously powdered.

The syrup has an agreeable flavour, for which alone it is employed. A fluidounce of the tincture of orange peel added to a pint of simple syrup, affords a preparation little inferior to the officinal, though the presence of the spirit may in some instances be objectionable.

Off. Prep. Confectio Aromatica, U. S., *Ed.*; Electuarium Cassiæ, *Dub.*; Pilulæ Rhei Compositæ, U. S. W.

SYRUPUS CROCI. *Lond., Ed. Syrup of Saffron.*

"Take of Saffron *ten drachms*; boiling Water *a pint* [Imperial measure]; Sugar [refined] *three pounds*. Macerate the Saffron in the Water for twelve hours, in a lightly covered vessel; then strain the liquor, and add the Sugar. *Lond.*

The *Edinburgh College* takes the same materials, in the same quantities, and proceeds in the manner directed for syrup of orange peel.

This is slightly stimulant, but is valued chiefly for its fine colour. *W.*

SYRUPUS IPECACUANHÆ. *U.S., Ed. Syrup of Ipecacuanha.*

"Take of Ipecacuanha, in coarse powder, *an ounce*; Diluted Alcohol *a pint*; Syrup *two pints*. Macerate the Ipecacuanha in the Alcohol for fourteen days, and filter. Evaporate the filtered liquor to two fluidounces, and again filter; then mix it with the syrup, and evaporate by means of a water-bath to the proper consistence.

"Syrup of Ipecacuanha may also be prepared by putting the Ipecacuanha, previously moistened with Diluted Alcohol, into an apparatus for displacement; pouring upon it gradually Diluted Alcohol until a pint of filtered liquor is obtained; then evaporating to two fluidounces, and completing the process as above directed." *U.S.*

"Take of Ipecacuanha, in coarse powder, *four ounces*; Rectified Spirit *one pint* [Imperial measure]; Proof Spirit and Water, of each, *fourteen fluidounces*; Syrup *seven pints*. Digest the Ipecacuanha in fifteen fluidounces of the Rectified Spirit at a gentle heat for twenty-four hours; strain, squeeze the residuum and filter. Repeat this process with the residuum and Proof Spirit, and again with the Water. Unite the fluids, and distil off the Spirit till the residuum amount to twelve ounces; add to the residuum five fluidounces of the Rectified Spirit, and then the Syrup." *Ed.*

By the process of the *U. S. Pharmacopœia*, a tincture of ipecacuanha is first formed with diluted alcohol, then concentrated, and incorporated with syrup. The alternative of preparing the tincture by maceration or percolation is allowed; but the latter mode should be resorted to only by those who have experience in conducting the process. The tincture is by concentration reduced chiefly to an aqueous solution of the active principles of ipecacuanha; and the water contained in it is evaporated after incorporation with the syrup. The *French Codex* dissolves the alcoholic extract of ipecacuanha in water, and then mixes it with syrup; but it is obvious that the *U. S.* process is preferable, as it spares the continued heat requisite to reduce the tincture to dryness. The *Edinburgh* process is unnecessarily complex; and the addition of the rectified spirit to the syrup, if thought necessary for its preservation, might have been dispensed with, had the direction been given to concentrate the syrup.

This syrup is chiefly applicable to the cases of children. One fluidounce of it, prepared according to the *U.S.* formula, should contain the virtues of fifteen grains of ipecacuanha. The dose of it, as an emetic, is for an adult from one to two fluidounces, for a child a year or two old, from one to two fluidrachms, to be repeated every fifteen or twenty minutes till it operates. As an expectorant, the dose for an adult is one or two fluidrachms, for a child from five to twenty minims. The *Edinburgh* syrup is somewhat, but not materially, weaker. *W.*

SYRUPUS KRAMERIÆ. *U.S. Syrup of Rhatany.*

"Take of Extract of Rhatany *two ounces*; Water *a pint*; Sugar *two*

pounds and a half. Dissolve the Extract in the Water and filter; then add the Sugar, and proceed in the manner directed for Syrup." *U. S.*

In making this syrup care should be taken to select the extract of rhatany as free as possible from insoluble matter; and that prepared according to the U. S. process will be found the best. (See *Extractum Kramerix*.) This preparation affords a convenient mode of exhibiting rhatany to infants. The dose for an adult is half a fluidounce, for a child a year or two old, twenty or thirty minims. *W.*

SYRUPUS LIMONIS. *U. S., Dub.* SYRUPUS LIMONUM. *Lond., Ed.* *Syrup of Lemons.*

"Take of Lemon-juice, strained, *a pint*; Sugar [refined] *two pounds*. Add the Sugar to the Juice, and proceed in the manner directed for Syrup." *U. S.*

"Take of Juice of Lemons, strained, *a pint* [Imperial measure]; Sugar [refined] *two pounds and a half*. Dissolve the Sugar in the Lemon Juice, with a gentle heat; then set it aside for twenty-four hours; afterwards remove the scum, and pour off the clear liquor from the dregs, if there be any." *Lond.*

"Take of Lemon-juice, freed of impurities by subsidence and filtration, *a pint* [Imperial measure]; Sugar *two pounds and a half*. Dissolve the Sugar in the Lemon-juice with the aid of a gentle heat, and after twenty-four hours' rest remove the same, and pour the clear liquor from the dregs." *Ed.*

"Take of Juice of fresh Lemons *two pints*. As soon as the dregs have subsided, put the Juice into a matrass, and subject it for fifteen minutes to the heat of boiling water. When cold, strain it through a sieve, and form a syrup." *Dub.*

This syrup forms a cooling and grateful addition to beverages in febrile complaints, and serves to conceal the taste of saline purgatives given in solution. *W.*

SYRUPUS MORI. *Lond.* *Syrup of Mulberries.*

"Take of Mulberry Juice, strained, *a pint* [Imperial measure]; Sugar [refined] *two pounds and a half*. Dissolve the Sugar in the Mulberry Juice, with a gentle heat, and proceed in the manner directed for Syrup of Lemons." *Lond.*

This may be used for the same purposes with lemon syrup. In like manner syrups may be prepared from various succulent fruits, such as *strawberries, raspberries, pineapples, &c.* When the juice is thick, it may be diluted with from one-third of its bulk to an equal bulk of water, previously to the addition of the sugar. In the preparation of *raspberry syrup*, which, as ordinarily made, is apt to gelatinize, M. Blondeau recommends that the strained juice be allowed to stand from eight to fifteen hours, according to the temperature, in order to ferment. The juice separates into two portions, the upper thick, the lower clear. The latter is to be separated by straining and made into a syrup with the usual proportion of sugar. These syrups are employed to flavour drinks, and are much used as grateful additions to carbonic acid water. *W.*

SYRUPUS PAPAVERIS. *Lond., Ed.* SYRUPUS PAPAVERIS SOMNIFERI. *Dub.* *Syrup of Poppies.*

"Take of Poppy [capsules] *three pounds*; Sugar [refined] *five pounds*; boiling Water *five gallons* [Imperial measure]. Boil down the Capsules in the Water to two gallons, and press strongly. Boil down the strained liquor again to four pints, and strain it while hot. Set it by for twelve hours

that the dregs may subside, then boil down the clear liquor to two pints, add the Sugar, and dissolve." *Lond.*

"Take of Poppy-heads, without the seeds, *one pound and a half*; Boiling Water *fifteen pints* [Imperial measure]; Pure Sugar *three pounds*. Slice the Poppy-heads, infuse them in the Water for twelve hours, boil down to five pints, strain and express strongly through calico, boil again down to two pints and a half; then add the Sugar and dissolve it with the aid of heat." *Ed.*

"Take of the Capsules of the White Poppy, dried, deprived of their seeds, and bruised, *seventeen ounces*; Boiling Water *two gallons*. Macerate the Capsules in the Water for twenty-four hours; then, by means of a water-bath, boil down to a gallon, and strongly express. Boil down the strained liquor again to two pints, and strain it while hot. Set it by for twelve hours that the dregs may subside; then boil down the clear liquor to a pint and form a syrup." *Dub.*

As the capsules contain variable proportions of the narcotic principle, the syrup prepared from them is necessarily of variable strength. It is, moreover, very apt to spoil. Its place might, with great propriety, be supplied by a syrup prepared from one of the salts of morphia, which would keep well and have the advantage of uniform strength. Four grains of the sulphate of morphia dissolved in a pint of syrup, would afford a preparation at least equal to the average strength of the syrup of poppies, and much more certain in its operation.

The syrup of poppies is employed, chiefly in infantile cases, to allay cough, quiet restlessness, relieve pain, and promote sleep. The dose is from half a fluidrachm to a fluidrachm for an infant, from half a fluidounce to a fluidounce for an adult. W.

SYRUPUS RHAMNI. *Lond., Ed., Dub. Syrup of Buckthorn.*

"Take of fresh Juice of Buckthorn [berries] *four pints* [Imperial measure]; Ginger, sliced, Pimento, in powder, each, *six drachms*; Sugar [refined] *four pounds*. Set by the Juice for three days that the dregs may subside, and then strain it. To a pint of the clear Juice add the Ginger and Pimento; then macerate for four hours with a gentle heat, and strain. Boil down the remainder of the Juice to a pint and a half; mix the liquors; add the Sugar and dissolve it." *Lond.*

The *Edinburgh* process is the same as the above.

"Take of the fresh Juice of Buckthorn Berries *two pints and a half*; Ginger Root, sliced, Pimento Berries, in powder, each, *three drachms*. Set by the Juice that the dregs may subside, and then strain it. Add the Ginger and Pimento to ten ounces of the clear Juice, macerate for twenty-four hours, and filter. Boil down the remaining Juice to a pint, mix the liquors, and form a syrup." *Dub.*

The syrup of buckthorn is a brisk cathartic, but having an unpleasant taste, and being apt to gripe violently, is very seldom employed. In Europe it is used occasionally as an adjunct to other medicines in cathartic and diuretic mixtures. The dose is from half a fluidounce to a fluidounce. The patient should drink freely of thin gruel, or other demulcent beverage, during its operation. W.

SYRUPUS RHEI. *U. S. Syrup of Rhubarb.*

"Take of Rhubarb, bruised, *two ounces*; boiling Water *a pint*; Sugar [refined] *two pounds*. Macerate the Rhubarb in the Water for twenty-four hours, and strain; then add the Sugar, and proceed in the manner directed for Syrup." *U. S.*

This is a mild cathartic, adapted to the cases of infants, to whom it may be given in the dose of one or two fluidrachms.

It has been proposed to form the *syrup* of rhubarb in the manner directed in the U. S. Pharmacopœia for the *aromatic syrup*, by first preparing a tincture with diluted alcohol, then evaporating the spirituous portion by means of a water-bath, and incorporating the remainder with sugar. It is questionable, however, whether this would be an improvement on the officinal formula; as, though a stronger syrup might be obtained, there would be some risk that a portion of the alcohol might remain, and render the preparation too stimulating to meet the indication for which it was originally intended.

W.

SYRUPUS RHEI AROMATICUS. U. S. *Aromatic Syrup of Rhubarb.*

"Take of Rhubarb, bruised, *two ounces and a half*; Cloves, bruised, Cinnamon, bruised, each, *half an ounce*; Nutmeg, bruised, *two drachms*; Diluted Alcohol *two pints*; Syrup *six pints*. Macerate the Rhubarb and aromatics in the Diluted Alcohol for fourteen days, and strain; then, by means of a water-bath, evaporate the liquor to a pint, and, while it is still hot, mix it with the Syrup previously heated.

"Aromatic Syrup of Rhubarb may also be prepared by putting the Rhubarb and Aromatics, previously reduced to coarse powder and moistened with Diluted Alcohol, into an apparatus for displacement; pouring upon them gradually Diluted Alcohol until two pints of filtered liquor are obtained; then evaporating to a pint, and completing the process as above directed." U. S.

Of these two modes of proceeding, the first should always be preferred by those not experienced in conducting the process of filtration by displacement. In preparing the syrup, the apothecary should be careful to employ aromatics of the best quality, and to effect the evaporation of the tincture, according to the officinal direction, by means of a water-bath.

The aromatic syrup of rhubarb is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel complaints of infants, which are so frequent in our cities during the summer season, and as a remedy for which the preparation, or one analogous to it, has been long in use under the name of *spiced syrup of rhubarb*. The dose for an infant with diarrhœa is a fluidrachm, repeated every two hours till the passages indicate by their colour that the medicine has operated.

W.

SYRUPUS RHŒADOS. Lond., Ed. SYRUPUS PAPAVERIS RHŒADIS. Dub. *Syrup of Red Poppy.*

"Take of Red Poppy [petals] *a pound*; boiling Water *a pint* [Imperial measure]; Sugar [refined] *two pounds and a half*. To the Water heated by a water-bath, gradually add the Petals, occasionally stirring; then, having removed the vessel, macerate for twelve hours; express the liquor, and when the dregs have subsided add the Sugar, and dissolve it." Lond.

The *Edinburgh* process is a close imitation of the London.

"Take of the fresh Petals of the Red Poppy *a pound*; boiling Water *twenty fluidounces*. Add the Petals gradually to the boiling Water; then, having removed the vessel from the fire, macerate with an inferior heat [between 90° and 100°] for twelve hours; express the liquor, and set it by that the dregs may subside; lastly, add the Sugar, and form a syrup." Dub.

The object of introducing the petals into water heated by a water-bath, is that they may shrink by being scalded, as otherwise they could not be completely immersed in the quantity of water directed. After this has been

accomplished, they should be immediately removed from the fire, lest the liquor should become too thick and ropy. The fine red colour of this syrup is its only recommendation. It has no medical virtues, and is very liable to ferment. W.

SYRUPUS ROSÆ. *Lond., Dub.* SYRUPUS ROSÆ CENTIFOLIÆ. *Ed. Syrup of Roses.*

“Take of Hundred-leaved roses, dried, *seven ounces*; Sugar [refined] *six pounds*; boiling Water *three pints* [Imperial measure]. Macerate the Petals in the water for twelve hours, and strain. Evaporate the strained liquor, by means of a water-bath, to two pints; then add the Sugar, and dissolve it.” *Lond.*

The *Dublin* process differs from the above only in having *four pints* [wine measure] of water, evaporating to two pints and a half, and using the proportion of sugar directed in its general formula. (See page 1145.)

“Take of fresh Damask-rose Petals *one pound*; boiling Water *three pints* [Imp. meas.]; Pure Sugar *three pounds*. Infuse the Petals in the Water for twelve hours, strain the liquor, and dissolve the Sugar in it with the aid of heat.” *Ed.*

This syrup is gently laxative, and, on account of its mildness, may be given with advantage to infants and persons of delicate habit. It is without the fragrance of the rose; but has a reddish colour which is rendered bright red by acids, and green or yellow by alkalies. The dose is from two fluidrachms to one or two fluidounces.

Off. Prep. Confectio Cassiæ, *Lond.*; Confectio Scammonii, *Lond.* W.

SYRUPUS ROSÆ GALLICÆ. *Ed. Syrup of Red Roses.*

“Take of dried Red-rose petals *two ounces*; boiling Water *one pint*; Pure Sugar *twenty ounces*. Proceed as for the Syrup of damask-rose.” *Ed.*

The syrup of red roses is mildly astringent; but is valued more for its fine red colour, on account of which it is occasionally added to mixtures.

Off. Prep. Electuarium Catechu, *Ed.* W.

SYRUPUS SARSAPARILLÆ. *Dub.* SYRUPUS SARZÆ. *Lond., Ed. Syrup of Sarsaparilla.*

“Take of Sarsaparilla, sliced, *fifteen ounces*; boiling Water *a gallon* [Imperial measure]; Sugar *fifteen ounces*. Macerate the Sarsaparilla in the Water for twenty-four hours; then boil down to four pints, and strain the liquor while hot; afterwards add the Sugar and evaporate to the proper consistence.” *Lond.*

The *Edinburgh* process is the same as the above.

The *Dublin College* obtains in the same manner four pints of a concentrated strained decoction, and prepares a syrup with this, according to the general directions of the College. (See page 1145.)

This syrup is necessarily a weak if not inert preparation; the virtues of sarsaparilla being only partially extracted by water, at least by the quantity of this menstruum ordinarily employed, and being injured or destroyed by long boiling. It is scarcely used in this country, our own compound syrup being preferred. W.

SYRUPUS SARSAPARILLÆ COMPOSITUS. *U.S. Compound Syrup of Sarsaparilla.*

“Take of Sarsaparilla, bruised, *two pounds*; Guaiacum Wood, rasped, *three ounces*; Hundred-leaved Roses, Senna, Liquorice Root, bruised, each, *two ounces*; Oil of Sassafras, Oil of Anise, each, *five minims*; Oil of Partridge-berry *three minims*; Diluted Alcohol *ten pints*; Sugar *eight pounds*.

Macerate the Sarsaparilla, Guaiacum Wood, Roses, Senna, and Liquorice Root in the Diluted Alcohol for fourteen days; then express and filter. Evaporate the tincture by means of a water-bath to four pints, filter, add the Sugar, and proceed in the manner directed for Syrup. Lastly, having rubbed the Oils with a small quantity of the Syrup, mix them thoroughly with the remainder.

“Compound Syrup of Sarsaparilla may also be prepared in the following manner:—Take of Sarsaparilla, ground into coarse powder, *two pounds*; Guaiacum Wood, rasped, *three ounces*; Hundred-leaved Roses, Senna, Liquorice Root, each, in coarse powder, *two ounces*; Oil of Sassafras, Oil of Anise, each, *five minims*; Oil of Partridge-berry *three minims*; Water *a sufficient quantity*; Sugar *eight pounds*. Mix the Sarsaparilla, Guaiacum Wood, Roses, Senna, and Liquorice Root with three pints of Water, and allow the mixture to stand for twenty-four hours. Then transfer the whole to an apparatus for displacement, and pour on Water gradually until one gallon of filtered liquor is obtained. Evaporate this to four pints; then add the Sugar, and proceed in the manner directed for Syrup. Lastly, having rubbed the Oils with a small portion of the Syrup, mix them thoroughly with the remainder.” *U. S.*

In the original edition of the U. S. Pharmacopœia published in 1820, a process for a syrup of sarsaparilla was adopted, intended to represent the famous French *Sirop de Cuisinier*. This was very much improved in the revised edition of the Pharmacopœia published in 1830; and the amended process is retained with very little alteration in the present edition, being the first of the two quoted above. In the original process, the sarsaparilla was subjected to long decoction with water, and the degree of concentration was indefinite. Now it has been proved that diluted alcohol more thoroughly extracts the acrid principles of the root, upon which its activity probably depends, than water, and that these principles are either dissipated or destroyed by the long continued application of a boiling heat.* In the present formula, therefore, which employs diluted alcohol as the menstruum, the root is more completely exhausted of its active matter; while the heat applied to the concentration, being no higher than is requisite for the evaporation of the alcohol, is insufficient to injure the preparation. The spirituous menstruum has, moreover, the advantage of not dissolving the inert *secula*, which encumbers the syrup prepared by decoction and renders it liable to spoil. At the late revision of the Pharmacopœia, the pale or hundred-leaved roses were very properly substituted for the red; as their slightly laxative property accords better with the character of the preparation. The operator should be careful to comply exactly with the directions of the Pharmacopœia in relation to the period of maceration, and the use of the water-bath. The essential oils being intended solely to communicate an agreeable flavour, are used in very small proportion. A syrup prepared according to this process has been for several years in use, and has given general satisfaction. The only objection to it is, that a portion of the resinous matter, extracted by the alcohol from the guaiacum wood, is deposited during the evaporation of the tincture; but this is separated by the filtration directed, and is therefore of no disadvantage to the preparation.

* See a paper by J. Hancock, M. D., republished in the *Journ. of the Phil. Col. of Pharm.* i. 295; a communication by M. Beral to the *Journal de Pharmacie*, xv. 657; another by M. Soubeiran in the same *Journal*, xvi. 38; and a paper by T. J. Husband in the *American Journ. of Pharm.* xv. 6.

It is perhaps unfortunate that the second process above quoted was adopted by the revisers of the Pharmacopœia. It yields a handsome syrup, containing a certain amount of the active matter of the sarsaparilla; but has been shown by the experiments of Mr. Husband, to have less of the sensible properties, and consequently, in all probability, of the medical virtues of the root, than the syrup prepared with diluted alcohol. (*Am. Journ. of Pharm.* xv. 6.) We would strongly advise an adherence to the first of the two official formulæ. But the practitioner should be aware that much of the sarsaparilla as it exists in the market is nearly or quite inert, and should be prepared to meet with disappointment in the use of this or any other preparation, unless satisfied of the good quality of the drug from which it is made.

The dose of the syrup of sarsaparilla is half a fluidounce, equivalent to somewhat less than a drachm of the root, to be taken three or four times a day. W.

SYRUPUS SCILLÆ. *U. S., Ed. Syrup of Squill.*

“Take of Vinegar of Squill *a pint*, Sugar [refined] *two pounds*. Add the Sugar to the Vinegar of Squill, and proceed in the manner directed for Syrup.” *U. S.*

“Take of Vinegar of Squill *three pints*; Pure Sugar, in powder, *seven pounds*. Dissolve the Sugar in the Vinegar of Squill, with the aid of a gentle heat and agitation.” *Ed.*

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. The dose is about a fluidrachm. In infantile cases of catarrh and other pectoral complaints, it is sometimes given, in the same dose, as an emetic. W.

SYRUPUS SCILLÆ COMPOSITUS. *U. S. Compound Syrup of Squill. Hive-syrup.*

“Take of Squill, bruised, Seneka, bruised, each, *four ounces*; Tartrate of Antimony and Potassa *forty-eight grains*; Water *four pints*; Sugar *three pounds and a half*. Pour the Water upon the Squill and Seneka, and having boiled to one-half, strain and add the Sugar; then evaporate to three pints, and, while the Syrup is still hot, dissolve in it the Tartrate of Antimony and Potassa.

“Compound Syrup of Squill, may be advantageously prepared in the following manner by those familiar with the process of displacement.

“Take of Squill, in coarse powder, Seneka, in coarse powder, each, *four ounces*; Tartrate of Antimony and Potassa *forty-eight grains*; Alcohol *half a pint*; Water *a sufficient quantity*; Sugar *three pounds and a half*. Mix the Alcohol with two pints and a half of Water, and macerate the Squill and Seneka in the mixture for twenty-four hours. Put the whole into an apparatus for displacement, and add as much Water as may be necessary to make the filtered liquor amount to three pints. Boil the liquor for a few minutes, evaporate to one-half, and strain; then add the Sugar, and evaporate until the resulting syrup measures three pints. Lastly, dissolve the Tartrate of Antimony and Potassa in the Syrup, while it is still hot.” *U. S.*

This is intended as a substitute for that very popular preparation commonly called *Coxe's Hive-syrup*, from which it differs chiefly in containing sugar instead of honey. Prepared according to the directions of the former Pharmacopœia, it invariably fermented, from the want of sufficient concentration. This defect was corrected at the last revision of the Pharmacopœia, when sugar was also substituted for honey, in consequence of the uncertain

consistence and constitution of the latter. It will be observed that two formulæ are given above, in the former of which the virtues of the squill and seneka are extracted by long boiling with water, in the latter, by percolation with water to which a small portion of alcohol has been added. Either of them will furnish an efficient product; but the latter is preferable when skillfully performed; as it avoids in great measure the injurious influence of boiling upon the seneka, exhausts both this and the squill more readily in consequence of the addition of alcohol to the menstruum, and affords a solution of their active principles less embarrassed with inert matters calculated to favour fermentation. In this process, the filtered liquor is raised to the boiling point in order to coagulate the albumen, after which the evaporation should be conducted at a lower temperature. But the inexperienced operator should always follow the first formula; for, if the percolation be not properly effected, the syrup will inevitably be weaker than it is designed to be.*

The compound syrup of squill combines the virtues of seneka, squill, and tartar emetic, of the last of which it contains one grain in every fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic, and may be given with advantage in mild cases of croup, in the latter stages of severe cases when the object is to promote expectoration, and in other pectoral affections in which the same indication is presented. As an emetic in inflammatory croup and infantile catarrh, we decidedly prefer a simple solution of tartar emetic in water. The dose of the compound syrup of squill is, for children, from ten drops to a fluidrachm, according to the age, and should be repeated in cases of croup every fifteen or twenty minutes till it vomits. As an expectorant for adults the dose is twenty or thirty drops. W.

SYRUPUS SENEGÆ. U. S. *Syrup of Seneka.*

"Take of Seneka, bruised, *four ounces*; Water *a pint*; Sugar [refined] *a pound*. Boil the Water with the Seneka to one-half, and strain; then add the Sugar, and proceed in the manner directed for Syrup. Syrup of Seneka may also be prepared in the following manner:—

"Take of Seneka, in coarse powder, *four ounces*; Water *a sufficient quantity*; Sugar *fifteen ounces*. Mix the Seneka with four fluidounces of Water and allow the mixture to stand for twelve hours; then put it into an apparatus for displacement, and gradually pour Water upon it until the liquid passes nearly tasteless. Evaporate the filtered liquor to half a pint, strain, and, having added the Sugar, proceed in the manner directed for Syrup." U. S.

The latter of these processes is preferable for an experienced operator; as it avoids the injury to the seneka resulting from long boiling; but they who are not practically acquainted with the process of percolation should employ the former.

* In the Pharmacopœia of 1830, this preparation was named *Mel Scillæ Compositum*, or compound honey of squill. The following was the official process: "Take of Squill, bruised, Seneka, bruised, each, *four ounces*; Tartrate of Antimony and Potassa *forty eight grains*; Clarified Honey *two pounds*. Pour the Distilled Water upon the Squill and Seneka, and boil to one-half; strain, and add the Clarified Honey; then boil down to three pints, in which dissolve the Tartrate of Antimony and Potassa." The preparation thus made was insufficiently concentrated, measuring only 20½° Baumé, instead of 30°, which is the proper standard of density for syrup. It therefore speedily fermented. By boiling, however, down to two pints instead of three, it will have the proper consistence, and will keep much better. But in this case only 32 grains of tartar emetic should be added, so that there may still be one grain of the antimonial to each fluidounce of the syrup.

This is an active preparation, and affords a very convenient mode of exhibiting seneka in pectoral complaints. It may be given as a stimulant expectorant in the dose of one or two fluidrachms. W.

SYRUPUS SENNÆ. *U. S., Lond., Ed. Syrup of Senna.*

“Take of Senna *two ounces*; Fennel-seed, bruised, *an ounce*; boiling Water *a pint*; Sugar *fifteen ounces*. Digest the Senna and Fennel-seed in the Water, with a gentle heat, for an hour; then strain, add the Sugar, and evaporate to the proper consistence.” *U. S.*

“Take of Senna *two ounces and a half*; Fennel [seeds], bruised, *ten drachms*; Manna *three ounces*; Sugar [refined] *fifteen ounces*; boiling Water *a pint* [Imperial measure]. Macerate the Senna and Fennel in the Water with a gentle heat for an hour. Strain the liquor and mix with it the Manna and Sugar; then boil down to the proper consistence.” *Lond.*

“Take of Senna *four ounces*; Boiling Water *one pint and four fluid-ounces* [Imperial measure]; Treacle *forty-eight ounces*. Infuse the Senna in the Water for twelve hours; strain and express strongly through calico, so as to obtain a pint and two fluidounces at least of liquid. Concentrate the Treacle in the vapour-bath as far as possible, or till a little taken out upon a rod becomes nearly concrete on cooling; and, while the Treacle is still hot, add the infusion, stirring carefully, and removing the vessel from the vapour-bath as soon as the mixture is complete. If Alexandrian Senna be used for this preparation, it must be carefully freed of Cynanchum leaves by picking it.” *Ed.*

The molasses in the Edinburgh syrup almost completely covers the taste of the senna; and the preparation, according to Dr. Christison, is very effectual, and seldom occasions nausea or griping. The U.S. and London processes are liable to the objection that considerable evaporation is necessary to bring the syrup to the proper consistence; so that, if a boiling heat be employed, the senna may be injured. This syrup is intended chiefly as a cathartic for children, to whom it may be given in the dose of one or two fluidrachms.* W.

SYRUPUS TOLUTANI. *U. S.* SYRUPUS TOLUTANUS. *Lond., Ed.*
SYRUPUS BALSAMI TOLUTANI. *Dub. Syrup of Tolu.*

“Take of Tincture of Tolu *a fluidounce*; Syrup *a pint and a half*. Mix the Tincture with the Syrup, and by means of a water-bath evaporate to the proper consistence.” *U. S.*

“Take of Balsam of Tolu *ten drachms*; boiling Water *a pint* [Imperial measure]; Sugar [refined] *two pounds and a half*. Boil the Balsam in the Water for half an hour, in a lightly-covered vessel, occasionally stirring, and strain the liquor when cold; then add the Sugar and dissolve it.” *Lond.*

The *Edinburgh College* prepares this syrup by adding gradually one

* Under the name of *fluid extract of senna*, a preparation, originally suggested by Mr. Charles Ellis, has been considerably used in this city. Mr. Duhamel, who has modified the original formula, prepares it in the following manner.—Macerate *eight ounces* of coarsely powdered senna with *a pint* of diluted Alcohol for twelve hours; then introduce it into a displacement apparatus, and gradually pour in water until *three pints* of liquid shall have passed. Evaporate with a gentle heat to *five fluidounces*, and, while the liquor is still hot, dissolve in it *five ounces* of sugar. Strain the liquor, and when it is cold add for each fluidounce *two drops* of the Oil of Fennel, dissolved in a little Hoffmann's Anodyne. The last mentioned ingredient serves to prevent the fluid extract from fermenting. Half a fluidounce is the dose for an adult. (*Am. Journ. of Pharm.* xiii. 290.)

ounce of the tincture of tolu to *two pounds* of simple syrup just prepared, and before it has become cold. The *Dublin College* pursues the same plan, using *an ounce* of the tincture to *a pint and a half* of syrup.

The London process affords a syrup with a finer flavour than that prepared with the tincture. The same portion of balsam is, according to Mr. Brande, usually employed in successive operations, and it long continues to impart odour and taste to boiling water. The quantity of the balsam is rather less than two grains in a fluidounce of the syrup, prepared according to the U. S. Pharmacopœia, which is about equal in strength to the Edinburgh and Dublin, and much stronger than the London. The syrup of tolu may, therefore, be considered inert as a medicine; and its only use is to communicate its pleasant flavour to mixtures.

W.

SYRUPUS VIOLÆ. *Ed., Dub. Syrup of Violets.*

“Take of Fresh Violets *one pound*; boiling Water *two pints and a half*; Pure Sugar *seven pounds and a half*. Infuse the flowers for twenty-four hours in the Water, in a covered glass or earthenware vessel; strain without squeezing, and dissolve the Sugar in the filtered liquor.” *Ed.*

“Take of the fresh Petals of the Violet *two pounds*; boiling Water *five pints*. Macerate for twenty-four hours; then filter the liquor through fine linen, without expression; lastly, add the Sugar [twenty-nine ounces for every pint of liquor] and form a syrup.” *Dub.*

This syrup has a deep blue colour and an agreeable flavour. It is said that its colour is most beautiful when it is prepared in well-cleaned pewter vessels; but the action of the metal has not been satisfactorily explained. As it is apt to fade by time, it is sometimes counterfeited with materials the colour of which is more permanent. The fraud may usually be detected by the addition of an acid or alkali, the former of which reddens the syrup of violets, the latter renders it green, while they produce no such change upon the counterfeit.

The syrup acts as a gentle laxative when given to infants in the dose of one or two fluidrachms; but it is used chiefly as a test of acids and alkalies. For the latter purpose, a syrup prepared from the juice of the red cabbage may be substituted in its place. It is very seldom kept in our shops.

W.

SYRUPUS ZINGIBERIS. *U.S., Lond., Ed., Dub. Syrup of Ginger.*

“Take of Tincture of Ginger *four fluidounces*; Syrup *a gallon*. Mix the Tincture with the Syrup, and by means of a water-bath evaporate to the proper consistence.” *U. S.*

The *London College* macerates *two ounces and a half* of sliced ginger, for four hours, in *a pint* [Imperial measure] of boiling water, and, having strained the infusion, adds *two pounds and a half* of refined sugar, and dissolves it. The *Edinburgh College* infuses *two ounces and a half* of bruised ginger, for four hours, in *a pint* [Imperial measure] of boiling water, strains, adds *two pounds and a half* of pure sugar, and dissolves it with the aid of heat. The *Dublin College* macerates *four ounces* of the bruised root, for twenty-four hours, in *three pints* of boiling water, filters the liquor, and adds *twenty-nine ounces* of refined sugar to each pint.

The process of the U. S. Pharmacopœia is the most easy, and affords a syrup in every respect equal to the others, without being like them encumbered with the mucilage and starch of the root. In order that it may be of

the proper strength, it is necessary that the tincture should have been made with the best Jamaica ginger.

The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impart flavour to drinks, particularly to carbonic acid water.

TINCTURÆ.

Tinctures.

Tinctures, in the pharmaceutical sense of the term, are solutions of medicinal substances in alcohol or diluted alcohol, prepared by maceration, digestion, or percolation. Solutions in ammoniated alcohol and ethereal spirit are embraced under the same denomination, but are severally distinguished by the addition of an epithet expressive of their peculiar character. The advantages of alcohol as a menstruum are, that it dissolves principles which are sparingly or not at all soluble in water, and contributes to their preservation when dissolved; while it leaves behind some inert substances which are dissolved by water. In no instance, however, is pure absolute alcohol employed. The United States Pharmacopœia directs it of the sp. gr. 0.835; the London and Edinburgh, 0.838; and the Dublin, 0.840. When of these densities it contains a considerable proportion of water, and is capable of dissolving more or less of substances which are insoluble in anhydrous alcohol, while its solvent power, in relation to bodies soluble in that fluid, is sufficient for all practical purposes. In numerous instances, diluted alcohol or proof spirit is preferable to alcohol itself; as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, at the same time that it is strong enough to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating. The diluted alcohol of the different Pharmacopœias is not of the same strength, that of the United States consisting of equal measures of officinal alcohol and water, and having the sp. gr. 0.935, while that of London has the sp. gr. 0.920, that of Edinburgh 0.912, and that of Dublin 0.919. The difference, however, is not very material. Alcohol or rectified spirit is preferred as the solvent, when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of the resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but by exercising an affinity for the alcohol which interferes with its solvent power. Thus water added to an alcoholic solution of one of these bodies, produces a precipitate by abstracting the alcohol from it. Diluted alcohol or proof spirit is employed, when the substance is soluble both in alcohol and water, or when one or more of the ingredients are soluble in the one fluid, and one or more in the other, as in the case of those vegetables which contain extractive or tannin, or the native salts of the organic alkalies, or gum united with resin or essential oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used.

In the preparation of the tinctures, the medicine should be in the dry state, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in the condition of a coarse than of a very fine powder; as

in the latter it is apt to agglutinate, and thus present an impediment to the penetration of the menstruum. When several substances differing in solubility are employed, they should be added successively to the spirit, those least soluble first, those most so last; as otherwise the menstruum might become saturated with the ingredient for which it has the strongest affinity, and thus be rendered incapable of dissolving a due proportion of the others.

Until recently, tinctures have been universally prepared by maceration or digestion. The Edinburgh College directs digestion to be continued usually for seven days. Our own Pharmacopœia follows that of London, in directing maceration at ordinary temperatures, and extending the period to two weeks. The latter plan is preferable, as it is most convenient, and equally effectual, the lower temperature being compensated by the longer maceration. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessel well stopped, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration; and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used till the maceration is completed, when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by first expressing it through linen, and subsequently filtering.

The plan of preparing tinctures by percolation or displacement has recently been extensively adopted; and has been found to answer an excellent purpose, when skilfully executed. In the last editions of the U.S. and Edinburgh Pharmacopœias, this mode of preparation has been given as an alternative in numerous instances; and would probably have been exclusively recommended in some, except for its liability to fail in the hands of inexperienced persons. The reader will find rules for the proper management of this process at pages 763 and 769.

Tinctures have been long in use on the Continent of Europe, and have recently been brought into notice in Great Britain, prepared by adding alcohol to the expressed juices of plants. They are sometimes called in England *preserved vegetable juices*. The tinctures of some of the narcotic plants might no doubt be advantageously prepared in this way, as those of conium, hyoscyamus, and belladonna. Mr. Squire and Mr. Bentley have paid particular attention to these preparations. According to Mr. Squire, the leaves only of the plants should be used, and in the case of biennial plants those exclusively of the second year's growth; and they should always be preferably collected when the plant is in full flower. Mr. Bentley recommends the following mode of preparation. To the expressed juice, after it has stood for twenty-four hours, and deposited its feculent matter, alcohol of 0.838 is to be added in the proportion of one part by measure to four of the juice; and, after another period of twenty-four hours, the liquor is to be filtered. The proportion of alcohol mentioned has been found sufficient for the preservation of the juice, while it causes the precipitation of all the suspended mucilaginous matter.

Tinctures should be kept in bottles accurately stopped, in order to prevent evaporation, which might, in some instances, be attended with serious inconvenience, by increasing their strength beyond the officinal standard.

Medicines are most conveniently administered in tincture, which act powerfully in small doses; as the proportion of alcohol in which they are dissolved is too minute to produce an appreciable effect. Those which require to be given in large doses, should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance

their beneficial operation. This remark is particularly applicable to chronic cases of disease, in which the use of tinctures is apt to result in the establishment of fatal habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effect upon the system.

The following general directions are given in the *U. S. Pharmacopœia*.

“Tinctures, when prepared by maceration, should be frequently shaken during the process, which should be conducted in glass vessels well stopped. When displacement is employed, great care should be taken to observe the directions given at page 4 [page 769, *U. S. Dispensatory*], so that the substances treated may be, as far as possible, exhausted of their soluble principles, and a perfectly clear tincture obtained. To those not familiar with this process, the plan of maceration is recommended.”

The *London College* states that “all tinctures should be prepared in closed glass vessels, and frequently shaken during the maceration.” The general directions of the *Edinburgh College*, which relate to the process of percolation, have been given at page 770. W.

TINCTURA ACONITI. *U. S. Tincture of Aconite.*

“Take of Aconite *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This tincture may also be prepared by thoroughly moistening the Aconite, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

This is a good preparation of aconite when made from the recently dried leaves, and may be given in the dose of twenty or thirty drops. W.

TINCTURA ALOËS. *U. S., Lond., Ed., Dub. Tincture of Aloes.*

“Take of Aloes, in powder, *an ounce*; Liquorice [extract] *three ounces*; Alcohol *half a pint*; Distilled Water *a pint and a half*. Macerate for fourteen days, and filter through paper. *U. S.*

The *London* process differs from the above only in the use of the Imperial, instead of the wine measure. The *Edinburgh College* takes *an ounce* of Socotrine or Indian Aloes, *three ounces* of liquorice, *twelve fluidounces* of rectified spirit, and *twenty-eight fluidounces* of water; digests for seven days; and filters the liquor, separated from the sediment. The *Dublin College* dissolves *an ounce and a half* of liquorice in *eight ounces* of boiling water; then adds *half an ounce* of Socotrine aloes and *eight fluidounces* of proof spirit, digests the whole for seven days, and filters.

The tincture of aloes of the former *U. S. Pharmacopœia* was prepared with the officinal diluted alcohol, without the addition of water. In the present edition it has been made to correspond with the tincture of the British Colleges. It is little more than an infusion, with the addition of sufficient alcohol to prevent spontaneous decomposition. The liquorice is added to cover the taste of the aloes; but it answers the end imperfectly; and the preparation, on account of its unpleasant bitterness, is little used, aloes being generally administered in the form of pill. The dose is from half a fluidounce to a fluidounce and a half. W.

TINCTURA ALOËS ET MYRRHÆ. *U. S., Ed. TINCTURA ALOËS COMPOSITA. Lond., Dub. Tincture of Aloes and Myrrh.*

“Take of Aloes, in powder, *three ounces*; Saffron *an ounce*; Tincture

of Myrrh *two pints*. Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *four ounces* of aloes, *two ounces* of saffron, and *two pints* [Imperial measure] of tincture of myrrh, and proceeds as above. The directions of the *Dublin College* correspond with those of our Pharmacopœia, except that Socotrine aloes is specified and the saffron omitted. The *Edinburgh College* takes *four ounces* of Socotrine or Indian aloes, *two ounces* of saffron, and *two pints* [Imperial measure] of tincture of myrrh; digests for seven days; and filters the clear "superincumbent" liquor.

This tincture is a modification of the *elixir proprietatis* of Paracelsus. The saffron, which has been retained in compliance with former prejudices, can add little to the efficacy of the preparation; and, being very expensive, has with great propriety been much reduced in the present *U. S.* formula. It serves, however, to impart a richness to the tincture, the want of which might be considered a defect by those accustomed to its use.

The tincture is purgative, tonic, and emmenagogue; and is considerably employed in chlorosis, and other disordered states of health in females, connected with suppressed, retained, or deficient menstruation, and with a constipated state of bowels. It may also be used as a stomachic laxative in cold, languid habits, independently of menstrual disorder. The dose is from one to two fluidrachms. W.

TINCTURA AMMONIÆ COMPOSITA. *Lond. Compound Tincture of Ammonia.*

"Take of Mastich *two drachms*; Rectified Spirit *nine fluidrachms*; Oil of Lavender *fourteen minims*; Oil of Amber *four minims*; Stronger Solution of Ammonia *a pint* [Imperial measure]. Macerate the Mastich in the Spirit that it may be dissolved, and pour off the clear tincture; then add the other ingredients, and shake them all together." *Lond.*

This is the *Spiritus Ammoniæ Succinatus* of the former *London Pharmacopœia*, and was intended as a substitute for the *eau de luce*. The tincture has a milky appearance, owing to the separation of the mastich from its alcoholic solution by the water of ammonia. Its properties are essentially those of its ammoniacal ingredient; the mastich having no medical action, and the oils of lavender and amber being in too small proportion to serve any other purpose than that of imparting flavour. It is used chiefly as a powerful stimulant applied to the nostrils, in cases of fainting and torpor. It had at one time considerable reputation as an antidote to the bite of venomous animals, but is not relied on at present. The dose for internal use is from ten to thirty drops. W.

TINCTURA ANGUSTURÆ. *Dub.* TINCTURA CUSPARIÆ. *Ed. Tincture of Angustura Bark.*

"Take of Angustura Bark, in coarse powder, *two ounces*; Proof Spirit *two pints*. Macerate for fourteen days; then filter." *Dub.*

The *Edinburgh College* takes *four ounces and a half* of the bark, and *two pints* [Imperial measure] of proof spirit, and proceeds as for the tincture of Peruvian bark.

This tincture contains the active principles of Angustura bark, and may be given in the dose of one or two fluidrachms. W.

TINCTURA ASSAFŒTIDÆ. *U. S., Lond., Ed.* TINCTURA ASSAFŒTIDÆ. *Dub. Tincture of Assafetida.*

"Take of Assafetida *four ounces*; Alcohol *two pints*. Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *five ounces* of assafetida, and *two pints* [Imperial measure] of rectified spirit, and proceeds as above. The *Edinburgh College*, with the same quantity of materials, digests for seven days, and filters the clear liquor. The *Dublin* process differs from that of the U. S. Pharmacopœia only in triturating the assafetida with *half a pint* of water previously to the addition of the alcohol.

This tincture becomes milky on the addition of water, in consequence of the separation of the resin. It possesses all the virtues of assafetida. The medium dose is a fluidrachm.

Off. Prep. Enema Fœtidum, *Dub.*

W.

TINCTURA AURANTII. *Lond., Ed.* *Tincture of Orange Peel.*

"Take of dried Orange Peel *three ounces and a half*; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, and filter." *Lond.*

"Take of Bitter Orange Peel, dried, *three ounces and a half*; Proof Spirit *two pints* [Imp. measure]. Digest for seven days, strain and express strongly, and filter the liquor. This tincture may be prepared by percolation, by cutting the Peel into small fragments, macerating it in a little of the Spirit for twelve hours, and beating the mass into a coarse pulp before putting it into the percolator." *Ed.*

It is the peel of the Seville orange which is intended by the *London College*; and the outer part only should be used, the inner whitish portion being inert. The tincture of orange peel is employed as a grateful addition to infusions, decoctions, and mixtures. It was omitted by mistake in the last edition of the *Dublin Pharmacopœia*, as it is an ingredient in one of the officinal preparations of that work.

Off. Prep. Mistura Ferri Aromatica, *Dub.*

W.

TINCTURA BELLADONNÆ. *U. S.* *Tincture of Belladonna.*

"Take of Belladonna [leaves] *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This tincture may also be prepared by thoroughly moistening the Belladonna, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

This tincture is an efficient preparation when made from the recently dried leaves; but the imported leaves are of very uncertain strength, and a tincture prepared from them is less to be relied upon than the extract. The dose is from fifteen to thirty drops.

W.

TINCTURA BENZOINI COMPOSITA. *U. S., Lond., Ed.*

TINCTURA BENZOËS COMPOSITA. *Dub.* *Compound Tincture of Benzoin.*

"Take of Benzoin *three ounces*; Purified Storax *two ounces*; Balsam of Tolu *an ounce*; Aloes, in powder, *half an ounce*; Alcohol *two pints*. Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *three ounces and a half* of benzoin, *two ounces and a half* of strained storax, *ten drachms* of balsam of Tolu, *five drachms* of aloes, and *two pints* [Imperial measure] of rectified spirit, and proceeds as above. The *Edinburgh College* takes *four ounces* of benzoin, *two ounces and a half* of balsam of Peru, *half an ounce* of East India aloes, and *two pints* [Imp. meas.] of rectified spirit, digests for seven days, pours off the clear liquor, and filters it. The *Dublin* process corresponds

with that of the U. S. Pharmacopœia, except that digestion for seven days is employed instead of maceration for fourteen.

This tincture is a stimulating expectorant, occasionally used in chronic catarrhal affections, but more frequently as a local application to indolent ulcers. It is the *balsamum traumaticum* of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as *baume de commandeur*, *Wade's balsam*, *Friar's balsam*, *Jesuits' drops*, &c. which were formerly in repute, and are still esteemed among the vulgar as pectorals and vulneraries. *Turlington's balsam*, which is a popular remedy in this country for such purposes, consists, as usually prepared in Philadelphia, of the ingredients of the official tincture, with the addition of Peruvian balsam, myrrh, and angelica root.* It is scarcely necessary to state, that the application of these remedies to fresh wounds must frequently prove injurious, by inducing too much inflammation, and thus preventing union by the first intention. The compound tincture of benzoin is decomposed by water. The dose is from thirty minims to two fluidrachms. A variety of *court plaster* is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin.

W.

TINCTURA BUCHU. *Dub.* TINCTURA BUCKU. *Ed.* *Tincture of Buchu.*

"Take of the Leaves of the *Diosma crenata* *two ounces*; Proof Spirit *a pint*. Macerate for seven days, and filter." *Dub.*

"Take of Bucku *five ounces*; Proof Spirit *two pints*. Digest for seven days, pour off the clear liquor, and filter it. This tincture may be conveniently and quickly made also by the process of percolation." *Ed.*

This tincture has the virtues of buchu leaves, and may be given in the dose of from one to four fluidrachms, either simply diluted with water, or as an addition to the infusion of the leaves.

W.

TINCTURA CAMPHORÆ. *U.S., Lond., Ed.* TINCTURA CAMPHORÆ sive SPIRITUS CAMPHORATUS. *Dub.* *Tincture of Camphor.*

"Take of Camphor *four ounces*; Alcohol *two pints*. Dissolve the Camphor in the Alcohol." *U.S.*

The *Dublin* process corresponds with the above. The *London College* dissolves *five ounces* of camphor in *two pints* [Imperial measure] of rectified spirit; the *Edinburgh*, *two ounces and a half* in *two pints* [Imperial measure].

This is used chiefly as an anodyne embrocation in rheumatic and gouty pains, chilblains, and the inflammation resulting from sprains and bruises. It may also be employed internally, due regard being paid to the stimulant properties of the alcohol. The camphor is precipitated by the addition of water, but may be suspended by the intervention of sugar. The dose is from five drops to a fluidrachm, first poured upon sugar, and then mixed with water.

Off. Prep. Linimentum Ammoniæ Compositum, *Ed.*

W.

* The following is the formula for *Turlington's balsam* adopted by the Philadelphia College of Pharmacy. "Take of Alcohol Oviij, Benzoin ℥xij, Liquid Storax ℥iv, Socotrine Aloes ℥j, Peruvian Balsam ℥ij, Myrrh ℥j, Angelica Root, ℥ss, Balsam of Tolu, ℥iv, Extract of Liquorice Root ℥iv. Digest for ten days and strain." *Journ. of the Phil. Col. of Pharm.* v. 28.

TINCTURA CANTHARIDIS. *U.S., Lond., Ed., Dub. Tincture of Spanish Flies.*

“Take of Spanish Flies, bruised, *an ounce*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This tincture may also be prepared by thoroughly moistening the flies, in powder, with Diluted Alcohol, allowing them to stand for twenty-four hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

The *London College* takes *four drachms* of the flies and *two pints* [Imperial measure] of proof spirit, macerates for fourteen days, and filters; the *Dublin*, *two drachms* of the former and a *pint and a half* of the latter, and digests for a week. The *Edinburgh College* takes the same proportions as the *London*, digests for seven days, strains, expresses the residuum strongly, and filters; or prepares the tincture by percolation, having previously moistened the coarsely powdered flies with a little of the spirit, and allowed them to stand for twelve hours.

This tincture is one of the most convenient forms for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis*.) It is occasionally employed externally as a rubefacient; but its liability to vesicate should be taken into consideration. The British tinctures are all too feeble, the strongest containing the virtues only of three quarters of a grain of cantharides in a fluidrachm. The dose of the *U. S.* tincture is from twenty drops to a fluidrachm, repeated three or four times a day.

W.

TINCTURA CAPSICI. *U.S., Lond., Ed., Dub. Tincture of Cayenne Pepper.*

“Take of Cayenne Pepper *an ounce*; Diluted Alcohol *two pints*. Macerate for fourteen days, and filter through paper.

“This tincture may also be prepared by thoroughly moistening the Cayenne Pepper, in powder, with Diluted Alcohol, putting it into an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

The *Dublin College* prepares this tincture according to the first of the above formulæ. The *London College* takes *ten drachms* of bruised Cayenne pepper and *two pints* [Imperial measure] of proof spirit, macerates for fourteen days, and filters; the *Edinburgh* takes the same proportions as the *London*, digests for seven days, strains, expresses, and filters; or prepares the tincture by percolation, having previously made the capsicum into a pulp with a little of the spirit.

This form of capsicum is a useful stimulant in very low states of the system with great gastric insensibility, as in malignant scarlet, and typhus fevers, and in the cases of drunkards. It may also be used as a gargle, diluted with rose water or some mucilaginous fluid. (See *Capsicum*.) Applied by means of a camel's hair pencil to the relaxed uvula, it sometimes produces contraction, and relieves prolapsus of that part. The dose is one or two fluidrachms.

W.

TINCTURA CARDAMOMI. *U.S., Lond., Ed. Tincture of Cardamom.*

“Take of Cardamom, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This tincture may also be prepared by thoroughly moistening the Car-

damom, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *three ounces and a half* of bruised cardamom, and *two pints* [Imperial measure] of proof spirit, macerates for fourteen days, and filters. The *Edinburgh College* takes *four ounces and a half* of the bruised seeds, and *two pints* [Imp. meas.] of proof spirit, digests for seven days, strains, expresses, and filters; or prepares the tincture by percolation, first grinding the seeds in a coffee-mill, and making them into a pulp with a little of the spirit.

This tincture is an agreeable aromatic, and may be advantageously added to tonic and purgative infusions. The dose is one or two fluidrachms.

Off. Prep. Tinctura Conii, *Ed.*

W.

TINCTURA CARDAMOMI COMPOSITA. *Lond., Ed., Dub.*
Compound Tincture of Cardamom.

"Take of Cardamom, Caraway, each, in powder, *two drachms and a half*; Cochineal, in powder, *a drachm*; Cinnamon, bruised, *five drachms*; Raisins *five ounces*; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, and filter." *Lond.*

The *Edinburgh College*, taking the same materials in the same quantities as the London, but bruised instead of powdered, digests for seven days, strains, expresses strongly, and filters. The same College allows the tincture to be prepared also by percolation; the solid materials being first beaten together, moistened with a little spirit, and allowed to stand for twelve hours before being introduced into the instrument. The *Dublin College* takes of cardamom seeds freed from their husks, and caraway, each, *two drachms*, of cinnamon *half an ounce*, and *two pints* of proof spirit, and proceeds in the same manner as the London College.

This is a very agreeable aromatic tincture, occasionally used as a carminative, in the dose of one or two fluidrachms, but more frequently as an addition to mixtures, infusions, &c., which it renders pleasant to the taste, and acceptable to the stomach.

Off. Prep. Decoctum Aloës Compositum, *Lond., Ed.*; Mistura Gentianæ Comp. *Lond.*

W.

TINCTURA CASCARILLÆ. *Lond., Ed., Dub.* *Tincture of Cascarilla.*

"Take of Cascarilla, in powder, *five ounces*; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, and filter." *Lond.*

The *Edinburgh College* employs *five ounces* of the bark, in moderately fine powder, and *two pints* [Imp. measure] of proof spirit; and proceeds by percolation or digestion as directed for the tincture of Peruvian bark. (See *Tinctura Cinchonæ*.) The *Dublin*, takes *four ounces* of the bark in coarse powder, and *two pints* of the menstruum, and macerates for seven days.

This tincture has the properties of cascarrilla, but is seldom if ever used in this country.

W.

TINCTURA CASSIÆ. *Ed.* *Tincture of Cassia.*

"Take of Cassia [Chinese Cinnamon], in moderately fine powder, *three ounces and a half*; Proof Spirit *two pints*. Digest for seven days, strain, express the residuum strongly, and filter. This tincture is more conve-

niently made by the process of percolation, the Cassia being allowed to macerate in a little of the Spirit for twelve hours before being put into the percolator." *Ed.*

The properties of this tincture are identical with those of tincture of cinnamon. (See *Tinctura Cinnamomi*.) W.

TINCTURA CASTOREI. *U.S., Lond., Ed.* TINCTURA CASTOREI ROSSICI. *Dub.* *Tincture of Castor.*

"Take of Castor, bruised, *two ounces*; Alcohol *two pints*. Macerate or seven days, express, and filter through paper." *U.S.*

The *London College* takes *two ounces and a half* of powdered castor, and *two pints* [Imperial measure] of rectified spirit, and macerates for fourteen days. The *Dublin College* directs *two ounces* of Russian castor, *two pints* of proof spirit, and maceration for a week. The *Edinburgh College* directs *two ounces and a half* of bruised castor, and *two pints* [Imp. meas.] of rectified spirit, and allows the tincture to be prepared either by digestion or percolation, like the tincture of cassia.

As castor yields little if any of its virtues to water, alcohol is a better solvent than proof spirit. It is said also to form a more grateful preparation. The Russian castor should always be preferred when attainable. This tincture is used for the same purposes with castor in substance. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CASTOREI AMMONIATA. *Ed.* *Ammoniated Tincture of Castor.*

"Take of Castor, bruised, *two ounces and a half*; Assafetida, in small fragments, *ten drachms*; Spirit of Ammonia *two pints* [Imperial measure]. Digest for seven days in a well-closed vessel; strain and express strongly the residuum; and filter the liquor." *Ed.*

This is an active stimulant and antispasmodic, applicable to cases of severe spasm of stomach, and to various hysterical and other nervous affections, unattended with inflammatory symptoms. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CATECHU. *U.S., Lond., Ed., Dub.* *Tincture of Catechu.*

"Take of Catechu *three ounces*; Cinnamon, bruised, *two ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper." *U.S.*

The *Dublin* process differs from the above only in the period of maceration, which is seven days. The *London College* takes *three ounces and a half* of catechu, *two ounces and a half* of cinnamon, and *two pints* [Imperial measure] of proof spirit, and macerates for fourteen days. The *Edinburgh College* takes *three ounces and a half* of catechu, in moderately fine powder; *two ounces and a half* of cinnamon, in fine powder; and *two pints* [Imp. meas.] of proof spirit; digests for seven days, strains, expresses strongly, and filters. This College prepares the tincture also by percolation, introducing the mixed powders into the percolator without previously moistening them with spirit.

This is a grateful astringent tincture, useful in all cases to which catechu is applicable, and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in diarrhœa. The dose is from thirty minims to three fluidrachms, which may be given

with sweetened water or some mucilaginous liquid, or in Port wine when this is not contra-indicated. W.

TINCTURA CINCHONÆ. U. S., Lond., Ed., Dub. *Tincture of Peruvian Bark.*

“Take of Peruvian Bark, in powder, *six ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This tincture may also be prepared by thoroughly moistening the Bark with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

“Take of Yellow Bark, in fine powder (or of any other species of Cinchona, according to prescription,) *eight ounces*; Proof Spirit *two pints* [Imperial measure]. Percolate the Bark with the Spirit, the Bark being previously moistened with a very little Spirit, left thus for ten or twelve hours, and then firmly packed in the cylinder. This tincture may also be prepared, though much less expeditiously, and with much greater loss, by the usual process of digestion, the bark being in that case reduced to coarse powder only.” *Ed.*

The *London College* orders *eight ounces* of yellow bark and *two pints* [Imp. meas.] of proof spirit, and macerates for fourteen days; the *Dublin*, *four ounces to two pints*, and digests for a week.

Of these tinctures, all, except the *Dublin*, are very properly made with a large proportion of bark; as, in the bitter tinctures, it is important that the alcohol should bear as small a proportion to the tonic principle as possible. Even the strongest, however, cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. The tincture of cinchona is used chiefly as an adjunct to the infusion or decoction of bark, or the solution of sulphate of quinia, to a dose of which it may be added in the quantity of from one to four fluidrachms. W.

TINCTURA CINCHONÆ COMPOSITA. U. S., Lond., Ed., Dub. *Compound Tincture of Peruvian Bark.*

“Take of Peruvian Bark, in powder, *two ounces*; Orange Peel, bruised, *an ounce and a half*; Virginia Snakeroot, bruised, *three drachms*; Saffron cut, Red Saunders rasped, each, *a drachm*; Diluted Alcohol *twenty fluid-ounces*. Macerate for fourteen days, express, and filter through paper.

“Compound Tincture of Peruvian Bark may be prepared from the same dry materials, by beating them well together, moistening them thoroughly with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until twenty fluidounces of filtered liquor are obtained.” *U. S.*

“Take of Cinchona lancifolia [Pale Bark], in powder, *four ounces*; dried Orange Peel *three ounces*; Virginia Snakeroot, bruised, *six drachms*; Saffron *two drachms*; Cochineal, in powder, *a drachm*; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, and filter.” *Lond.*

The *Edinburgh College* takes the same materials in the same quantities as the *London*, but specifies yellow bark, which it orders in coarse powder, if digestion, in fine powder, if percolation be employed. *Serpentaria* is directed in moderately fine powder. The process is conducted either by digesting for seven days, straining, expressing strongly, and filtering; or by percolation in the same way as compound tincture of cardamom. The

Dublin College specifies the pale bark, and directs *two scruples* of cochineal in place of the red saunders, and *half an ounce* of orange peel; in other respects, the process corresponds with the first formula of the U. S. Pharmacopœia.

This is the preparation commonly known by the name of *Huxham's tincture of bark*. It is an excellent stomachic cordial, and, though too feeble in the principles of cinchona to serve as a substitute for that tonic when its full effect upon the system is required, may be very usefully employed as an addition to the decoction or infusion, or to the salts of quinia, in low forms of fever, particularly in malignant intermittents, and typhoid remittents. Huxham was in the habit of uniting with it the *elixir of vitriol*, the aromatic sulphuric acid of the Pharmacopœias. The dose is from one to four fluidrachms. W.

TINCTURA CINNAMOMI. U. S., Lond., Ed., Dub. *Tincture of Cinnamon.*

"Take of Cinnamon, bruised, *three ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This tincture may also be prepared by thoroughly moistening the Cinnamon, in powder, with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." U. S.

The *London College* takes *three ounces and a half* of cinnamon, and *two pints* [Imperial measure] of proof spirit, and macerates for fourteen days; the *Dublin*, *three ounces and a half* of cinnamon and *two pints* of proof spirit, and macerates for fourteen days; the *Edinburgh*, *three ounces and a half* of the former, in moderately fine powder, and *two pints* [Imp. meas.] of the latter, and proceeds by percolation or digestion as in the preparation of tincture of cassia.

This tincture has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures, and astringent infusions or decoctions. The dose is from one to three or four fluidrachms.

Off. Prep. Infusum Digitalis, U. S.

W.

TINCTURA CINNAMOMI COMPOSITA. U. S., Lond., Ed. *Compound Tincture of Cinnamon.*

"Take of Cinnamon, bruised, *an ounce*; Cardamom [seeds], bruised, *half an ounce*; Ginger, bruised, *three drachms*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"Compound Tincture of Cinnamon may be prepared from the same dry materials, in the state of powder, by moistening them thoroughly with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." U. S.

The *London College* orders *an ounce* of cinnamon, *half an ounce* of cardamom, *two drachms and a half* of long pepper, *the same quantity* of ginger, and *two pints* [Imperial measure] of proof spirit, and macerates for two weeks. The *Edinburgh College* directs *an ounce* of cinnamon in coarse or fine powder, according as digestion or percolation is followed, *an ounce* of bruised cardamom seeds, *three drachms* of finely ground long pepper, and *two pints* [Imp. meas.] of proof spirit; and allows the tincture to be prepared either by digestion for seven days, straining, expressing, and filtering, or by percolation in the manner directed for compound tincture of cardamom; preferring, however, the latter mode.

This is a very warm aromatic tincture, useful in flatulence, spasm of the stomach, and gastric debility. The dose is one or two fluidrachms. W.

TINCTURA COLCHICI COMPOSITA. *Lond. Compound Tincture of Colchicum.*

"Take of Colchicum Seeds, bruised, *five ounces*; Aromatic Spirit of Ammonia *two pints* [Imperial measure]. Macerate for fourteen days, and filter." *Lond.*

This is the *Spiritus Colchici Ammoniatus* of the former London Pharmacopœia. It may be employed for the same purposes as the wine of colchicum, in cases which require or admit of an active stimulant. The dose is from thirty drops to a fluidrachm. W.

TINCTURA COLCHICI SEMINIS. *U. S. TINCTURA COLCHICI.* *Lond., Ed. TINCTURA SEMINUM COLCHICI.* *Dub. Tincture of Colchicum Seed.*

"Take of Colchicum Seed, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Colchicum Seed, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* orders *five ounces* of the bruised seeds, *two pints* [Imperial measure] of proof spirit, and maceration for two weeks; the *Dublin*, *two ounces* of the former and *a pint* of the latter, and the same maceration. The *Edinburgh College* takes *five ounces* of the seeds finely ground in a coffee-mill, and *two pints* [Imp. meas.] of proof spirit; and prepares the tincture in the same manner as the tincture of Peruvian bark, either by percolation or digestion; preferring, however, the former process.

This tincture possesses the active properties of colchicum, and may be given whenever that medicine is indicated; but the wine, which contains less alcohol, is generally preferred. The dose is from half a fluidrachm to two fluidrachms. The tincture is sometimes used as an embrocation in rheumatic, gouty, and neuralgic pains. W.

TINCTURA COLOMBÆ. *U. S., Dub. TINCTURA CALUMBÆ.* *Lond., Ed. Tincture of Columbo.*

"Take of Columbo, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Columbo, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours; then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *three ounces* of sliced columbo, and *two pints* [Imperial measure] of proof-spirit; the *Dublin*, *two ounces and a half* of the former, and *two pints* of the latter; and both macerate for fourteen days. The *Edinburgh College* takes *three ounces* of columbo, in small fragments or moderately fine powder, according as digestion or percolation is followed, and *two pints* [Imp. meas.] of proof-spirit; and prepares the tincture either by digesting for seven days, decanting, expressing, and filtering, or by the process of percolation, allowing the powder to be macerated with a little spirit for six hours before being put into the cylinder.

The tincture of columbo of the U. S. Pharmacopœia was, with great propriety, considerably increased in strength at the last revision. The larger the proportion of the tonic is to the alcohol in these bitter tinctures, the better are they calculated to meet the indications for which they are usually prescribed. When the proportion is very small, the tonic power of the bitter is overwhelmed by the stimulant influence of the alcohol. The tincture of columbo may be added to tonic infusions or decoctions, to increase their stimulant power; but, like all the other bitter tinctures, should be used with caution. The dose is from one to four fluidrachms. W.

TINCTURA CONII. *U.S., Lond., Ed., Dub. Tincture of Hemlock.*

“Take of Hemlock Leaves *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter, through paper.

“This Tincture may also be prepared by thoroughly moistening the Hemlock Leaves, in powder, with Diluted Alcohol, allowing them to stand for twenty-four hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained. *U. S.*

The *London College* takes *five ounces* of the dried leaves, *an ounce* of bruised cardamom, and *two pints* [Imperial measure] of proof-spirit, and macerates for fourteen days; the *Dublin*, *two ounces* of the leaves, *an ounce* of the seeds, and *a pint* of proof spirit, and macerates for a week.

“Take of fresh leaves of Conium *twelve ounces*; Tincture of Cardamom *half a pint*; Rectified Spirit *one pint and a half*. Bruise the Hemlock Leaves, express the juice strongly; bruise the residuum, pack it firmly in a percolator; transmit first the Tincture of Cardamom, and then the Rectified Spirit, allowing the spirituous liquors to mix with the expressed juice as they pass through; add gently water enough to the percolator for pushing through the spirit remaining in the residuum. Filter the liquor after agitation.” *Ed.*

The tincture of hemlock necessarily partakes of the uncertainty of the dried leaves from which it is prepared. There can be little doubt that the tincture of the *Edinburgh College*, made from the fresh leaves and their expressed juice, is the most efficient. A preparation made by adding one measure of alcohol to four of the expressed juice, has been used in England under the name of *preserved juice of hemlock*, and is probably quite equal to the *Edinburgh* tincture. (See page 1159.) The U. S. Pharmacopœia has very properly excluded cardamom from this preparation; as it can have little influence upon its medical effects, and tends to obscure the odour which is an indication of the activity of the tincture. A strong odour of conia should be emitted by the tincture upon the addition of potassa. The dose is from thirty minims to a fluidrachm. W.

TINCTURA CROCI. *Ed. Tincture of Saffron.*

“Take of Saffron, chopped fine, *two ounces*; Proof Spirit *two pints* [Imperial measure]. This Tincture is to be prepared like Tincture of Cinchona, either by percolation or by digestion, the former method being the most convenient and expeditious.” *Ed.*

This tincture possesses all the properties of saffron; but is of little other use than to impart colour to mixtures. The dose is from one to three fluidrachms. W.

TINCTURA CUBEÆ. U.S., Lond. TINCTURA PIPERIS CUBEÆ. Dub. *Tincture of Cubebs.*

"Take of Cubebs, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Cubebs, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." U.S.

The London College takes *five ounces* of powdered cubebs, and *two pints* [Imperial measure] of proof spirit; the Dublin, *four ounces* of the former and *two pints* of the latter; and both macerate for fourteen days.

This may be used as a carminative, and has been applied with advantage to the treatment of gonorrhœa in the advanced stages. The dose is one or two fluidrachms.

W.

TINCTURA DIGITALIS. U.S., Lond., Ed., Dub. *Tincture of Foxglove.*

"Take of Foxglove *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Foxglove, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." U.S.

The London College directs *four ounces* of the dried leaves, *two pints* [Imperial measure] of proof spirit, and maceration for fourteen days; the Dublin, *two ounces* of the dried leaves (the larger being rejected) and *a pint* of proof spirit, and maceration for a week.

"Take of Digitalis, in moderately fine powder, *four ounces*; Proof Spirit *two pints* [Imp. meas.]. This tincture is best prepared by the process of percolation, as directed for the tincture of capsicum. If forty fluid-ounces of spirit be passed through, the density is 0.944, and the solid contents of a fluidounce amount to twenty-four grains. It may also be made by digestion." Ed.

In preparing this tincture, great attention should be paid to the selection of the leaves, according to the rules laid down under the head of Digitalis. From a neglect of these, it is apt to be weak or inefficient. We have observed, in our own experience, a decided superiority in the tincture prepared from carefully preserved leaves imported from England. The expressed juice of the leaves, preserved by means of alcohol, would probably be found a powerful preparation. (See page 1159.) The tincture of foxglove possesses all the virtues of that narcotic, and affords a convenient method of administering it, especially in mixtures. The dose is from ten to twenty drops, to be repeated two or three times a day, and increased, if necessary, with great caution. (See *Digitalis*.)

W.

TINCTURA GALBANI. Dub. *Tincture of Galbanum.*

"Take of Galbanum, cut into small pieces, *two ounces*; Proof Spirit *two pints*. Digest for seven days, and filter." Dub.

The tincture of galbanum is analogous in properties to that of assafetida, but weaker and less nauseous. It is very seldom used. The dose is from one to three fluidrachms.

W.

TINCTURA GALLÆ. U.S., Lond. TINCTURA GALLARUM. Ed., Dub. *Tincture of Galls.*

“Take of Galls, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by thoroughly moistening the Galls, in powder, with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained.” U. S.

The *London College* directs *five ounces* of powdered galls, two pints [Imperial measure] of proof spirit, and maceration for fourteen days; the *Dublin*, *four ounces* of the galls, *two pints* of the spirit, and digestion for seven days. The *Edinburgh College* takes the same quantity of materials as the *London*, and prepares the tincture either by digestion or percolation as directed for tincture of capsicum.

The tincture of galls is powerfully astringent; but is more used as a test than as a medicine. The dose is from one to three fluidrachms. W.

TINCTURA GENTIANÆ COMPOSITA. U.S., Lond., Ed., Dub. *Compound Tincture of Gentian.*

“Take of Gentian, bruised, *two ounces*; Orange Peel [dried] *an ounce*; Cardamom [seeds], bruised, *half an ounce*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared from the same dry materials, in the state of powder, by moistening them thoroughly with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained.” U. S.

The *Dublin* process corresponds with the first U. S. process. The *London College* takes *two ounces and a half* of sliced gentian, *ten drachms* of dried orange-peel, *five drachms* of bruised cardamom, and *two pints* [Imperial measure] of proof spirit, and macerates for fourteen days. The *Edinburgh College* takes *two ounces and a half* of bruised gentian, *ten drachms* of bruised dried bitter orange-peel, *six drachms* of canella in moderately fine powder, *half a drachm* of bruised cochineal, and *two pints* [Imp. meas.] of proof spirit; digests for seven days, strains, expresses strongly, and filters; or prepares the tincture by percolation as directed for the compound tincture of cardamom.

This is an elegant bitter, much used in dyspepsia, and as an addition to tonic mixtures in debilitated states of the digestive organs, or of the system generally. There is, however, much danger of its abuse, especially in chronic cases. The dose is one or two fluidrachms. W.

TINCTURA GUAIACI. U.S., Lond., Ed., Dub. *Tincture of Guaiac.*

“Take of Guaiac, in powder, *half a pound*; Alcohol *two pints*. Macerate for fourteen days, and filter through paper.” U. S.

The *London College* takes *seven ounces* of guaiac and *two pints* [Imperial measure] of rectified spirit, and proceeds as above. The *Edinburgh College* orders the same quantity of materials as the *London*, and digests for a week. The *Dublin College* directs *four ounces* of guaiac and *two pints* of alcohol, and macerates for a week.

This tincture is given in chronic rheumatism and gout, in the dose of from one to three fluidrachms three or four times a day. As it is decomposed by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension. The

following is a form of tincture of guaiac which the late Dr. Dewees found very efficient in the cure of suppression of the menses, and dysmenorrhœa. "Take of the best Guaiac, in powder, *four ounces*; Carbonate of Soda or of Potassa *one drachm and a half*; Pimento, in powder, *an ounce*; Diluted Alcohol *a pound*. Digest for a few days." The dose is a teaspoonful three times a day, to be gradually increased if necessary. Within our own experience, this remedy has proved highly useful in painful menstruation, given in the intervals of the attacks. The quantity of alkaline carbonate is too small to produce any sensible effect, and the pimento can act only as a spice; so that the virtues of the tincture reside in the guaiac, and the official tincture would probably be found equally effectual. W.

TINCTURA GUAIACI AMMONIATA. *U.S., Ed., Dub.* TINCTURA GUAIACI COMPOSITA. *Lond.* *Ammoniated Tincture of Guaiac.*

"Take of Guaiac, in powder, *four ounces*; Aromatic Spirit of Ammonia *a pint and a half*. Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *seven ounces* of guaiac, and *two pints* [Imperial measure] of aromatic spirit of ammonia, and macerates for fourteen days. The *Edinburgh College* takes the same quantity of materials as the London, and digests for seven days in a well-closed vessel. The *Dublin* corresponds with the *U. S.* process, except that the maceration continues only for a week.

This tincture is very celebrated in the treatment of chronic rheumatism. It is more stimulating and is thought to be more effectual than the preceding. Like that, it is decomposed by water, and should be administered in some viscid or tenacious vehicle which may hold the guaiac in suspension. The dose is one or two fluidrachms. W.

TINCTURA HELLEBORI. *U.S., Lond.* TINCTURA HELLEBORI NIGRI. *Dub.* *Tincture of Black Hellebore.*

"Take of Black Hellebore, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Black Hellebore, in powder, with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *five ounces* of the bruised root, and *two pints* [Imperial measure] of proof-spirit, and macerates for fourteen days; the *Dublin*, *four ounces* of the former and *two pints* of the latter, and macerates for a week.

This tincture possesses the properties of black hellebore, and, upon the recommendation of Dr. Mead, has been much used in suppression of the menses. It is said to be peculiarly applicable to cases in which the grade of action is too high for the use of chalybeates. At best, however, it is an uncertain remedy, and should always be administered with caution, as it is sometimes violent in its action. The dose is from thirty minims to a fluidrachm, to be taken night and morning. W.

TINCTURA HUMULI. *U.S., Dub.* TINCTURA LUPULI. *Lond.* *Tincture of Hops.*

"Take of Hops *five ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper." *U. S.*

The *London College* takes *six ounces* of hops and *two pints* [Imperial

measure] of proof spirit, macerates for fourteen days, and filters. The *Dublin* process differs from ours only in the omission of expression.

Hops are so light and bulky, that, in the proportion directed, they absorb almost all the spirit, which, after the requisite maceration, can be separated only by strong pressure. As this absorption of the spirit obstructs its proper action on all parts of the hops, it is necessary that the mixture should be frequently stirred during the maceration. By thoroughly drying the hops and rubbing them between the hands, or by cutting and bruising them, they may be brought to a state of division which will in a great measure obviate the disadvantages alluded to. As the virtues of hops depend chiefly on the lupulin, and as the quantity of this substance is not the same in different parcels, the tincture is necessarily unequal in strength; and the tincture of lupulin itself is greatly preferable. (See *Tinctura Lupulinæ*.) The tincture of hops is tonic and narcotic, and has been proposed as a substitute for laudanum when the latter disagrees with the patient; but little reliance can be placed upon it. The condition of disease to which it appears to be best adapted, is the wakefulness, attended with tremors and general nervous derangement, to which habitual drunkards are liable, and which frequently precedes an attack of delirium tremens. The dose is from one to three fluidrachms.

W.

TINCTURA HYOSCYAMI. *U. S., Lond., Ed., Dub.* *Tincture of Henbane.*

“Take of Henbane Leaves *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This tincture may also be prepared by thoroughly moistening the Henbane Leaves, in powder, with Diluted Alcohol, allowing them to stand for twenty-four hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

The *London College* takes *five ounces* of the dried leaves, and *two pints* [Imperial measure] of proof spirit, and macerates for fourteen days; the *Dublin*, *five ounces* of the former and *two pints* of the latter, and digests for a week. The *Edinburgh College* orders the same amount of materials, the henbane being in moderately fine powder, and directs the tincture to be prepared either by digestion, or, preferably, by percolation as directed for the tincture of capsicum.

This tincture may be advantageously substituted, as an anodyne and soporific, for that of opium, when the latter disagrees with the patient, or is objectionable on account of its property of inducing constipation. When the tincture of henbane purges, as it sometimes does, it may be united with a very small proportion of laudanum. The dose is a fluidrachm. The expressed juice preserved by means of alcohol may be used for the same purposes as the tincture. (See page 1159.)

W.

TINCTURA IODINI. *U. S.* **TINCTURA IODINEI.** *Ed.* **IODINII TINCTURA.** *Dub.* *Tincture of Iodine.*

“Take of Iodine *an ounce*; Alcohol *a pint*. Dissolve the Iodine in the Alcohol.

The *Edinburgh College* directs *two ounces and a half* of iodine to be dissolved, with the aid of a gentle heat and agitation, in *two pints* [Imperial measure] of rectified spirit. The *Dublin College* takes *two scruples* of iodine, and *an ounce*, by weight, of rectified spirit, mixes and dissolves the iodine with the aid of heat. Both Colleges direct the tincture to be kept in well-stopped bottles.

These tinctures contain so nearly the same proportion of iodine that, for all practical purposes, they may be considered identical. They are of very nearly the strength of the tincture employed by Coindet, which contained one part of iodine to twelve of alcohol by weight; while the U. S. tincture contains one part of the former to about 12·7 parts of the latter. It is best to prepare the tincture in small quantities at a time; as the iodine reacts on the alcohol, especially when exposed to solar light, uniting with its hydrogen to form hydriodic acid, which in its turn is said to produce a portion of hydriodic ether by reaction with the alcohol. The iodine should be thoroughly dried before being weighed out. The tincture should be kept in well-stopped bottles in order to prevent the evaporation of the alcohol, and the consequent crystallization of the iodine.

The tincture of iodine has a deep brown colour. Sixteen minims, equal to about thirty-five drops, contain one grain of iodine. It is at present less used internally than it formerly was, in consequence of an impression that it is apt to irritate the stomach. Water decomposes the tincture, and when this is swallowed, it is supposed that the iodine is precipitated upon the mucous membrane. It is now, therefore, almost exclusively employed as an external application. Undiluted, it acts as a powerful irritant to the skin, producing inflammation, desquamation of the cuticle, &c. Nevertheless, it is much used in this state in erysipelas, chilblains, and other cases of cutaneous and subcutaneous inflammation, and often with very happy effects. But its application requires some caution; and in erysipelas, we are in the habit rather of surrounding the inflamed surface with a border of the tincture, embracing a portion of both the sound and the diseased skin, so as to prevent the progress of the inflammation, than of attempting a complete cure by covering the whole surface affected. It is most conveniently applied by means of a camels'-hair pencil. Diluted with the camphorated tincture of soap, or other alcoholic liquid, it is sometimes employed as an embrocation in scrofulous tumours and other affections requiring the peculiar influence of iodine. The dose of the tincture is from ten to twenty drops, which may be gradually increased to thirty or forty drops, three times a day. It may be given in sweetened water, and still better in wine when this is not contraindicated. W.

TINCTURA IODINI COMPOSITA. U. S. TINCTURA IODINII COMPOSITA. *Lond. Compound Tincture of Iodine.*

“Take of Iodine *half an ounce*; Iodide of Potassium *an ounce*; Alcohol *a pint*. Dissolve the Iodine and Iodide of Potassium in the Alcohol,”
U. S.

The *London College* takes *an ounce* of iodine, *two ounces* of iodide of potassium, and *two pints* [Imperial measure] of rectified spirit; macerates till they are dissolved, and filters.

The U. S. tincture is rather stronger than the London, the wine pint employed in the former containing about one-fifth less than the Imperial pint employed in the latter. The difference, however, is of no great practical importance. The advantage of this tincture over the simple tincture above described is, that the former may be diluted with water without decomposition; so that, when it is swallowed, iodine is not precipitated upon the mucous coat of the stomach, and will not, therefore, be so likely to produce gastric irritation. This is a good theoretical recommendation; but we are by no means confident that the difference of the two preparations in irritating properties will be found very striking in practice. The compound tincture of iodine may be given internally for all the purposes which iodine

is capable of answering. The dose is from twenty to forty drops, to be gradually increased if necessary. It should be diluted with water when administered. W.

TINCTURA JALAPÆ. U. S., Lond., Ed., Dub. Tincture of Jalap.

“Take of Jalap, in powder, *eight ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by moistening the Jalap thoroughly with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

The *London College* takes *ten ounces* of jalap, and *two pints* [Imperial measure] of proof spirit; the *Dublin*, *eight ounces* of the former and *two pints* of the latter; and both continue the maceration for two weeks. The *Edinburgh College* orders *seven ounces* of jalap, in moderately fine powder, and *two pints* [Imp. meas.] of proof spirit, and allows the tincture to be prepared either by digestion or percolation, as directed for tincture of cinchona.

This tincture possesses the medical virtues of jalap, and is sometimes added to cathartic mixtures in the quantity of one or two fluidrachms, to increase their activity. W.

TINCTURA KINO. Lond., Ed., Dub. Tincture of Kino.

“Take of Kino, in powder, *three ounces and a half*; Rectified Spirit *two pints* [Imperial measure]. Macerate for fourteen days, and filter.” *Lond.*

The *Edinburgh College* takes the same ingredients in the same proportion as the *London*, and digests for a week; the *Dublin*, *three ounces* of kino, and *two pints* of proof spirit, and macerates for a week.

This tincture very frequently becomes gelatinous if kept, and at length almost entirely loses its astringency. The circumstances which favour this change, and the characters of the chemical reaction which takes place remain to be investigated. Until some mode is discovered of obviating this evil, the tincture seems scarcely to be a proper object for officinal direction. The dose is one or two fluidrachms. It is used chiefly as an addition to cretaceous and other astringent mixtures, in diarrhœa. W.

TINCTURA KRAMERIÆ. U. S. Tincture of Rhatany.

“Take of Rhatany, in powder, *six ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This tincture may also be prepared by moistening the Rhatany thoroughly with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

According to F. Boudet, the tincture of rhatany sometimes gelatinizes like that of kino. (*Journ. de Pharm. N. S. i. 338.*) We have not ourselves seen this result in the specimens which have come under our notice. This is a good preparation of rhatany in cases which admit of the use of small quantities of alcohol. The dose is one or two fluidrachms. W.

TINCTURA LACTUCARII. Ed. Tincture of Lactucarium.

“Take of Lactucarium, in fine powder, *four ounces*; Proof Spirit *two pints*. This tincture is best prepared by percolation as directed for tincture

of myrrh; but may also be prepared by digestion with coarse powder of *Lactucarium*." *Ed.*

The dose of this tincture is from thirty minims to two fluidrachms. W.

TINCTURA LOBELIÆ. U. S., Ed. *Tincture of Lobelia.*

"Take of Lobelia [the herb] *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Lobelia, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *Edinburgh College* directs *five ounces* of Lobelia, in moderately fine powder, and *two pints* [Imperial measure] of proof spirit; and states that the tincture is best prepared by percolation as directed for tincture of capsicum, though it may also be made by digestion.

This tincture possesses the emetic and narcotic properties of lobelia, and is sometimes used in asthma, in the dose of one or two fluidrachms, repeated every two or three hours till its effects are experienced. The emetic dose is half a fluidounce. W.

TINCTURA LOBELIÆ ÆTHEREA. Ed. *Ethereal Tincture of Lobelia.*

"Take of dry Lobelia, in moderately fine powder, *five ounces*; Spirit of Sulphuric Ether *two pints* [Imperial measure]. This tincture is best prepared by percolation, as directed for tincture of capsicum; but it may also be obtained by digestion in a well-closed vessel for seven days." *Ed.*

The stimulant operation of the ether in this preparation can scarcely favour the relaxing and nauseating action for which lobelia is usually employed. The dose is the same as that of the alcoholic tincture. W.

TINCTURA LUPULINÆ. U. S. TINCTURA LUPULI. Ed. *Tincture of Lupulin.*

"Take of Lupulin *four ounces*; Alcohol *two pints*. Macerate for fourteen days, and filter through paper." *U. S.*

"Take *any convenient quantity* of Hops, recently dried; separate by friction and sifting the yellowish-brown powder attached to their scales. Then take of this powder *five ounces*, and of rectified spirit *two pints*, and prepare the tincture by percolation or digestion, as directed for tincture of capsicum." *Ed.*

This is much superior to the tincture of hops of the first United States Pharmacopœia, in the place of which it was introduced into the second edition. In the original preparation, a certain quantity of hops was directed, from which the lupulin was to be separated by beating, and then digested in alcohol. As hops contain a variable proportion of lupulin, a tincture thus prepared must be of unequal strength; an objection to which the tincture of hops, however prepared, is liable. Besides, the amount of lupulin contained in any quantity of hops upon which alcohol can conveniently act, is too small in proportion to the alcohol, to afford a tincture of the due strength. The present tincture is, therefore, in all respects, preferable. The dose is one or two fluidrachms, to be given in sweetened water or some mucilaginous fluid. W.

TINCTURA MOSCHI. Dub. *Tincture of Musk.*

"Take of Musk, in powder, *two drachms*; Rectified Spirit *a pint*. Digest for seven days, and filter." *Dub.*

This tincture is much too feeble in musk to be capable of producing beneficial effects in any dose which would not contain too large a quantity of alcohol. Musk should always be given in substance. W.

TINCTURA MYRRHÆ. U. S., Lond., Ed., Dub. Tincture of Myrrh.

“Take of Myrrh, bruised, *four ounces*; Alcohol *three pints*. Macerate for fourteen days, and filter through paper.” U. S.

The *London College* takes *three ounces* of powdered myrrh, and *two pints* [Imperial measure] of rectified spirit, and proceeds as above. The *Dublin College* takes *three ounces* of bruised myrrh, *a pint and a half* of proof spirit, and *half a pint* of rectified spirit; and digests for a week.

“Take of Myrrh, in moderately fine powder, *three ounces and a half*; Rectified Spirit *two pints* [Imperial measure]. Pack the Myrrh very gently without any spirit in a percolator; then pour on the Spirit; and when thirty-three fluidounces have passed through, agitate well to dissolve the oleo-resinous matter which first passes, and which lies at the bottom. This tincture is much less conveniently obtained by the process of digestion for seven days.” Ed.

Undiluted alcohol is preferable, as a solvent of myrrh, to that fluid mixed with water; because it forms a perfectly clear solution, which is not attainable with the latter menstruum. The addition of water to the tincture renders it turbid. The tincture of myrrh is scarcely ever used internally. As a local application it is employed to stimulate indolent and foul ulcers, and promote the exfoliation of bones, and, diluted with water, is applied to spongy gums, aphthous sore mouth, and ulcerations of the throat. The dose, as a stimulant expectorant and emmenagogue, is from half a fluidrachm to a fluidrachm.

Off. Prep. Tinctura Aloës et Myrrhæ. U. S., Lond., Ed., Dub. W.

TINCTURA NUCIS VOMICÆ. Dub. Tincture of Nux Vomica.

“Take of Nux Vomica, rasped, *two ounces*; Rectified Spirit *eight ounces*. Macerate for seven days, and filter.” Dub.

The tincture is not an eligible form for administering the nux vomica, as it is equally uncertain with the medicine in substance, and has the disadvantage of excessive bitterness. The alcoholic extract, or strychnia is preferable. The dose of the tincture is from five to twenty drops. It is sometimes employed externally in cases of local paralysis. W.

TINCTURA OLEI MENTHÆ PIPERITÆ. U. S. Tincture of Oil of Peppermint. Essence of Peppermint.

“Take of Oil of Peppermint *two fluidounces*; Alcohol *a pint*. Dissolve the Oil in the Alcohol.” U. S.

This is a very popular preparation, which has long been kept in the shops under the name of *essence of peppermint*, and has now for the first time been introduced into the Pharmacopœia. It affords a very convenient method of hastily administering a dose of the oil of peppermint, being of such a strength that, when dropped on loaf sugar, it may be taken without inconvenience by the patient. The dose is from ten to twenty drops, which may be given as just mentioned, or mixed with sweetened water. W.

TINCTURA OLEI MENTHÆ VIRIDIS. U. S. Tincture of Oil of Spearmint. Essence of Spearmint.

“Take of Oil of Spearmint *two fluidounces*; Alcohol *a pint*. Dissolve the Oil in the Alcohol.” U. S.

The remarks made upon the preceding article are applicable also to the present. The dose of the *essence of spearmint* is from twenty to forty drops.

W.

TINCTURA OPII. U. S., Lond., Ed., Dub. *Tincture of Opium. Laudanum.*

“Take of Opium, in powder, *two ounces and a half*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.” U. S.

The process of the *Dublin College* corresponds with the above. The *London College* takes *three ounces* of hard opium, in powder, and *two pints* (Imperial measure) of proof spirit, macerates for fourteen days, and filters.

“Take of Opium, sliced, *three ounces*; Rectified Spirit *one pint and seven fluidounces* [Imperial measure]; Water *thirteen fluidounces and a half*. Digest the Opium in the Water at a temperature near 212° for two hours; break down the Opium with the hand; strain and express the infusion; macerate the residuum in the Rectified Spirit for about twenty hours, and then strain and express very strongly. Mix the watery and spirituous infusions, and filter.

“This Tincture is not easily obtained by the process of percolation; but when the Opium is of fine quality, it may be prepared thus. Slice the Opium finely; mix the Spirit and Water; let the Opium macerate in fourteen fluidounces of the mixture for twelve hours, and then break it down thoroughly with the hand; pour the whole pulpy mass and fluid into a percolator, and let the fluid part pass through; add the rest of the Spirit without packing the Opium in the cylinder, and continue the process of percolation till two pints are obtained.” Ed.

The proportion of opium in the several officinal formulæ is so nearly the same that the resulting tinctures may be considered identical. The apparent difference between the formulæ of the London and Edinburgh Colleges and ours will vanish, when the relative value of the Imperial measure which they employ and the wine measure of our Pharmacopœia is estimated. The drying and powdering of the opium directed in all the Pharmacopœias except the Edinburgh, is clearly a useful provision; as it ensures greater uniformity in the strength of the tincture. Crude opium contains very variable proportions of moisture; and laudanum prepared from a moist specimen will obviously be much weaker than that from an equal weight of the dried. The pulverization ensures the previous drying of the drug, and is thus useful independently of the greater facility which it gives to the action of the menstruum. It is troublesome, however, and is often neglected. Innovation in so important a preparation, and one in which uniformity of strength is so desirable, should be avoided unless clearly shown to be necessary. For these reasons we object to the Edinburgh formula, and greatly prefer the old standard of the U. S., London, and Dublin Pharmacopœias.

In the United States and Great Britain, this tincture is universally known by the name of *laudanum*. As this term was formerly applied to other preparations of opium, and still continues to be so on the Continent of Europe, the tincture is sometimes distinguished by the epithet *liquidum*, which, however, is seldom used in this country. *Tinctura Thebaica* is another title by which the preparation is known.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter. Allowing the opium to be wholly exhausted of its active principles, one grain would be

represented by 12·8 minims, according to the U. S. formula; but a small quantity of morphia has been detected in the residuary matter, so that the tincture is rather weaker than the proportion of opium employed would indicate.

The tincture of opium is used for all the purposes to which opium itself is applied. (See *Opium*.) The dose, equivalent to a grain of opium, is about thirteen minims, or twenty-five drops. Mr. Phillips, in his translation of the London Pharmacopœia of 1836, states that, by evaporating the tincture and also by determining the quantity of opium left undissolved, he found the preparation to contain one grain of opium in 19 minims; and this quantity, therefore, is given as the dose equivalent to a grain of opium. But this mode of calculation is obviously fallacious; as the portion of the drug dissolved is much more active than that left behind by the menstruum. It should be recollected that a fluidrachm or teaspoonful of laudanum (sixty minims) will afford, on an average, about one hundred and twenty drops. Laudanum, when long kept, with occasional exposure to the air, becomes thick, in consequence of the evaporation of a portion of the alcohol, and the deposition of opium. If given in this state, it often acts with unexpected energy; and cases of death have resulted in infants from its use in doses which would have been entirely safe if the tincture had been clear.

Off. Prep. Enema Opii, Lond., Ed., Dub.; Linimentum Opii, Lond., Dub. W.

TINCTURA OPII ACETATA. U. S. *Acetated Tincture of Opium.*

“Take of Opium *two ounces*; Vinegar *twelve fluidounces*; Alcohol *half a pint*. Rub the Opium with the Vinegar; then add the Alcohol, and, having macerated for fourteen days, express, and filter through paper.” U. S.

This preparation was introduced into the second edition of our Pharmacopœia as a substitute for the *Acetum Opii* or *black drop* of the original work, the advantages of which it was supposed to possess, without being liable to the same objection of uncertainty of strength. The *Acetum Opii*, however, having maintained its standing in the estimation of the profession and of the public, was restored, in the last edition of the Pharmacopœia, to its officinal rank, but so modified as to ensure a preparation as uniform as is consistent with the variable quality of the opium used. (See page 776.) At the same time the formula for the acetated tincture was retained, as affording a useful preparation of the drug. It was originally employed by Dr. Joseph Hartshorne of Philadelphia.

The acetated tincture of opium may often be advantageously used in cases in which laudanum or opium itself produces unpleasant effects, such as nausea and vomiting, intense headache, great nervous disorder, &c.; but the introduction of the salts of morphia into use has in a great measure superseded the necessity of the preparation. The dose is ten minims, or about twenty drops, equivalent to a grain of opium. W.

TINCTURA OPII AMMONIATA. Ed. *Ammoniated Tincture of Opium.*

“Take of Benzoic Acid, and Saffron, chopped, of each, *six drachms*; Opium, sliced, *half an ounce*; Oil of Anise *a drachm*; Spirit of Ammonia *two pints* [Imperial measure]. Digest for seven days, and then filter.” Ed.

This tincture is used in Scotland under the title of *paregoric elixir*, but differs both in composition and strength from the preparation known by that name in the United States. Some doubts have been entertained whether it contains morphia. It is well known that ammonia precipitates

morphia from its solutions; but a great excess of ammonia redissolves the precipitate. To decide the question, Mr. Gilbert, of Nottingham, submitted several portions of the tincture to a chemical examination, and was unable to detect morphia in them. (*Med. Exam.* iv. 493, from *Ed. Med. and Surg. Journ.*) But we are not informed by the experimenter, whether the tincture was prepared, as directed by the College, with the Edinburgh spirit of ammonia, which is a strong alcoholic solution of the caustic alkali, or with the London spirit, which is a comparatively feeble solution of carbonate of ammonia. In the former case the ammonia, according to Dr. Christison, is in sufficient excess to hold the morphia in solution. At best, however, the preparation is of doubtful propriety; as, if the ammoniacal spirit should not happen to have the due strength, or if the ammonia should escape or become carbonated by exposure, the strength of the tincture would be affected. It is employed in spasmodic complaints, such as whooping cough and asthma. Eighty minims should contain about a grain of opium. W.

TINCTURA OPII CAMPHORATA. *U. S., Ed., Dub.* TINCTURA CAMPHORÆ COMPOSITA. *Lond.* *Camphorated Tincture of Opium. Paregoric Elixir.*

"Take of Opium, in powder, Benzoic Acid, each, *a drachm*; Oil of Anise, *a fluidrachm*; Clarified Honey *two ounces*; Camphor *two scruples*; Diluted Alcohol *two pints*. Macerate for fourteen days, and filter through paper." *U. S.*

The *London College* takes *fifty grains* of camphor, *seventy-two grains* of powdered opium, *the same quantity* of benzoic acid, *a fluidrachm* of oil of anise, and *two pints* [Imperial measure] of proof spirit, and proceeds as above. The *Dublin* process agrees with that of the *U. S. Pharmacopœia*, omitting the honey, and employing *a drachm* instead of *a fluidrachm* of oil of anise. The *Edinburgh College* directs *fifty grains* of camphor, *four scruples* of opium, *four scruples* of benzoic acid, *a fluidrachm* of oil of anise, and *two pints* [Imp. meas.] of proof spirit, and digests for a week.

This is the well known *paregoric elixir*. It is a very pleasant anodyne and antispasmodic, much used to allay cough in chronic catarrh, asthma, consumption, pertussis, &c.; to relieve nausea and slight pains in the stomach and bowels; to check diarrhœa; and, in infantile cases, to procure sleep. Half a fluidounce of the *U. S.*, *London*, and *Dublin* tincture contains rather less than a grain of opium; of the *Edinburgh*, about a grain. Li- quorice, which was directed in the former *U. S. Pharmacopœia*, has been omitted in the present edition, in consequence of giving to the preparation the dark colour of laudanum, and thus leading to mistake. The dose for an infant is from five to twenty drops, for an adult from one to two fluidrachms.*

Off. Prep. Mistura Cascarillæ Composita, *Lond.*

W.

* The following formulæ have been adopted by the Philadelphia College of Pharmacy for the preparation of the two compound tinctures of opium, so much used under the names of *Bateman's drops* and *Godfrey's cordial*. So long as these nostrums are employed, it is important that they should be prepared in a uniform manner, and of a certain strength; as serious consequences may happen from diversity in the formulæ, when so active a substance as opium is the chief ingredient. Such diversity has existed to a very great extent; so much so that in one formula for Bateman's drops the quantity of opium was seven and a half grains to the pint, while in another it exceeded one hundred grains. It was in order to remedy this evil, that the College was induced to adopt the formulæ here presented.

"*Bateman's pectoral drops.* Take of Diluted Alcohol Cong. iv., Red Saunders, rasped, ℥ij. Digest for twenty-four hours, filter, and add of Opium in powder ℥ij, Catechu in

TINCTURA QUASSIÆ. U. S., Ed., Dub. Tincture of Quassia.

“Take of Quassia, rasped, *two ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by moistening the Quassia thoroughly with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.”
U. S.

The *Edinburgh College* takes *ten drachms* of quassia, and *two pints* [Imperial measure] of proof spirit, and digests for a week; the *Dublin*, an *ounce* of quassia, and *two pints* of proof spirit, and macerates for a week.

In the formula of the last edition of the *U. S. Pharmacopœia*, the proportion of the quassia to the menstruum was very judiciously doubled. A tonic tincture can scarcely contain too large a proportion of the active ingredient. The *Edinburgh* and *Dublin* preparations are much too feeble.

This tincture may be employed as an addition to tonic infusions or mixtures, in the quantity of one or two fluidrachms at a dose. It is a pure and intense bitter. W.

TINCTURA QUASSIÆ COMPOSITA. Ed. Compound Tincture of Quassia.

“Take of Cardamom seeds, bruised, and Cochineal, bruised, of each, *half an ounce*; Cinnamon, in moderately fine powder, and Quassia, in chips, of each, *six drachms*; Raisins *seven ounces*; Proof Spirit *two pints* [Imperial measure]. Digest for seven days, strain the liquor, express strongly the residuum, and filter. This tincture may also be obtained by percolation as directed for compound tincture of cardamom, provided the Quassia be rasped or in powder.” *Ed.*

This is tonic and aromatic, and may be given in the dose of one or two fluidrachms. W.

TINCTURA RHEI. U. S., Ed. Tincture of Rhubarb.

“Take of Rhubarb, bruised, *three ounces*; Cardamom [seeds], bruised, *half an ounce*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by thoroughly moistening the Rhubarb and Cardamom, in powder, with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

The *Edinburgh College* takes *three ounces and a half* of rhubarb, in moderately fine powder, *half an ounce* of bruised cardamom seeds, and *two pints* [Imperial measure] of proof spirit; and prepares the tincture, like that of cinchona, either by percolation or by digestion. W.

powder $\mathfrak{z}\text{ij}$., Camphor $\mathfrak{z}\text{ij}$., Oil of Anise $\mathfrak{ss}\text{iv}$., Digest for ten days.” This preparation is about equal in strength to the Camphorated tincture of opium or paregoric elixir of the *U. S. Pharmacopœia*, containing about two grains of opium to the fluidounce.

“*Godfrey's cordial.* Take of Tincture of Opium Oiss. , Molasses (from the sugar refiners) Oxxvj. , Alcohol Oij ., Water Oxxvj. , Carbonate of Potassa $\mathfrak{z}\text{iiiss.}$, Oil of Sassafras $\mathfrak{ss}\text{iv}$., Dissolve the Carbonate of Potassa in the Water, add the Molasses, and heat over a gentle fire till they simmer; take off the scum which rises, and add the Laudanum and Oil of Sassafras, having previously mixed them well together.” This preparation contains the strength of rather more than one grain of opium in a fluidounce. (*Journ. of the Phil. Col. of Pharm.* v. 26 and 27.)

TINCTURA RHEI COMPOSITA. *Lond., Dub. Compound Tincture of Rhubarb.*

"Take of Rhubarb, sliced, *two ounces and a half*; Liquorice Root, bruised, *six drachms*; Ginger, sliced, Saffron, each, *three drachms*; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, and filter." *Lond.*

The *Dublin College* employs *two ounces* of rhubarb, *half an ounce* of cardamom seeds, husked and bruised, *half an ounce* of bruised ginger, *two drachms* of saffron, and *two pints* of proof spirit; and macerates for seven days. W.

TINCTURA RHEI ET ALOES. *U. S., Ed. Tincture of Rhubarb and Aloes.* ELIXIR SACRUM. *Sacred Elixir.*

"Take of Rhubarb, bruised, *ten drachms*; Aloes, in powder, *six drachms*; Cardamom [seeds], bruised, *half an ounce*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper." *U. S.*

The *Edinburgh College* takes *an ounce and a half* of rhubarb, in moderately fine powder, *six drachms* of Socotrine or East India aloes, in moderately fine powder, *five drachms* of bruised cardamom seeds, and *two pints* [Imperial measure] of proof spirit; mixes the dry materials, and proceeds as for the tincture of cinchona. W.

TINCTURA RHEI ET GENTIANÆ. *U. S., Ed. Tincture of Rhubarb and Gentian.*

"Take of Rhubarb, bruised, *two ounces*; Gentian, bruised, *half an ounce*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Rhubarb and Gentian, in powder, with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *Edinburgh College* takes *two ounces* of rhubarb, in moderately fine powder, *half an ounce* of gentian, finely cut or in coarse powder, and *two pints* [Imperial measure] of proof spirit; mixes the powders, and proceeds as for tincture of cinchona.

The above tinctures of rhubarb are all in a greater or less degree purgative, stomachic, and tonic; but, except in low states of the system, or in cases of individuals accustomed to the use of ardent spirits, they are too feebly cathartic in proportion to their stimulant power, to be advantageously employed, unless as adjuvants to other medicines. Combined with the neutral salts or other laxatives, or with tonic and stomachic infusions, mixtures, &c., they serve to render them warmer and more cordial to the stomach, and often prove beneficial in flatulent colic, dyspepsia, the costiveness of cold irritable habits, diarrhœa, and other analogous complaints. One of them is to be preferred to another, according as its peculiar composition may, in the judgment of the practitioner, appear to adapt it to the circumstances of the case under treatment. In low forms of fever, when the indication is to evacuate the bowels, and at the same time stimulate the patient, the simple tincture (*Tinctura Rhei*) may be very advantageously used in doses of two or three fluidrachms, repeated at proper intervals till it operates. The ordinary dose of these tinctures, as purgatives, is from half a fluidounce to a fluidounce; as stomachics, from one to two or three fluidrachms. W.

TINCTURA RHEI ET SENNÆ. U. S. *Tincture of Rhubarb and Senna.*

“Take of Rhubarb, bruised, *an ounce*; Senna *two drachms*; Coriander [seeds], bruised, Fennel-seed, bruised, each, *a drachm*; Red Saunders, rasped, *two drachms*; Saffron, Liquorice [extract], each, *half a drachm*; Raisins, deprived of their seeds, *half a pound*; Diluted Alcohol *three pints*. Macerate for fourteen days, express, and filter through paper.”
U. S.

This is the stomachic so well known, and so much used in this country, under the name of *Warner's gout cordial*. It is a feeble purgative, usually very acceptable to the stomach, and well adapted to cases of costiveness, with gastric uneasiness, in persons of a gouty habit, and accustomed to the free use of wine or other stimulant drink. The dose is from half a fluidounce to two fluidounces.
W.

TINCTURA SANGUINARIÆ. U. S. *Tincture of Bloodroot.*

“Take of Bloodroot, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by thoroughly moistening the Bloodroot, in powder, with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

This will prove emetic in the dose of three or four fluidrachms; but it is rather intended to act as a stimulant to the stomach, or as an alterative, for which purposes it may be given in the quantity of from thirty to sixty drops.
W.

TINCTURA SAPONIS CAMPHORATA. U. S. *LINIMENTUM SAPONIS. Lond., Ed., Dub. Camphorated Tincture of Soap.*

“Take of Soap [Castile soap], in shavings, *four ounces*; Camphor *two ounces*; Oil of Rosemary *half a fluidounce*; Alcohol *two pints*. Digest the Soap with the Alcohol by means of a water-bath till it is dissolved; then filter, and add the Camphor and Oil.” *U. S.*

The *London* and *Dublin Colleges* take *three ounces* of soap, *an ounce* of camphor, and *a pint* [*sixteen fluidounces, Lond.*] of spirit of rosemary. The former dissolves the camphor in the spirit, then adds the soap, and macerates with a gentle heat till it is dissolved; the latter digests the soap in the spirit till it is dissolved, and then adds the camphor. The *Edinburgh College* takes *five ounces* of Castile soap, *two ounces and a half* of camphor, *six fluidrachms* of oil of rosemary, and *two pints* [Imperial measure] of rectified spirit; digests the soap in the spirit for three days, adds the camphor and oil, and agitates briskly.

It is necessary, in preparing this tincture, that the soap employed should not have been made with animal oil, as otherwise the preparation will not be fluid at ordinary temperatures. The soap indicated by the *U. S. Pharmacopœia* is that “prepared from soda and olive oil,” commonly called *Castile soap*. Even with this, the *U. S. tincture* coagulates upon cooling, and requires the addition of a portion of water to enable it to retain the liquid form. If made with hard old Castile soap, the tincture becomes a soft solid upon cooling, and requires a temperature of 84° to render it again perfectly fluid; and the least proportion of water adequate to cause the preparation to remain fluid between 45° and 50° is one part, by measure, to ten of the alcohol. Three fluidounces of water, added to the quantity of

materials indicated in the formula, are sufficient to prevent the tincture from coagulating at ordinary temperatures; and the same result may be obtained by using alcohol of the sp. gr. 0.848 instead of the officinal. The preparation is usually called *soap liniment*, a name which more properly belongs to the *Linimentum Saponis Camphoratum* of the Pharmacopœia, or common *opodeldoc*.

The camphorated tincture of soap is much used, as an anodyne and gently rubefacient embrocation, in sprains, bruises, and local rheumatic or gouty pains.

Off. Prep. Linimentum Opii, *Lond., Dub.*

W.

TINCTURA SCILLÆ. *U. S., Lond., Ed., Dub.* Tincture of Squill.

“Take of Squill *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by thoroughly moistening the Squill, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol, until two pints of filtered liquor are obtained.” *U. S.*

The *London College* takes *five ounces* of recently dried squill, and *two pints* [Imperial measure] of proof spirit, and macerates for fourteen days; the *Dublin*, *four ounces* of the former and *two pints* of the latter, and macerates for seven days. The *Edinburgh College* takes *five ounces* of coarsely powdered squill, and *two pints* [Imp. meas.] of proof spirit; and proceeds by percolation, as for the tincture of Peruvian bark, but without pressing the pulp firmly in the percolator. The College also allows the tincture to be prepared by digestion from the sliced bulb.

The tincture possesses all the virtues of squill, and may be given for the same purposes, whenever the spirituous menstruum is not objectionable. The dose as an expectorant or diuretic is from ten to twenty minims (twenty to forty drops), and the latter quantity usually nauseates. W.

TINCTURA SENNÆ COMPOSITA. *Lond., Dub.* Compound Tincture of Senna.

“Take of Senna *three ounces and a half*; Caraway, bruised, *three drachms and a half*; Cardamom, bruised, *a drachm*; Raisins *five ounces*; Proof Spirit *two pints* [Imperial measure]. Macerate for fourteen days, and filter.” *Lond.*

The *Dublin College* takes a pound of senna, an ounce and a half of caraway, half an ounce of cardamom seeds without the capsules, and a gallon of proof spirit, and proceeds as above.

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in costiveness attended with flatulence, and in atonic gout, especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. The dose is from two fluidrachms to a fluidounce or more. W.

TINCTURA SENNÆ ET JALAPÆ. *U. S.* TINCTURA SENNÆ COMPOSITA. *Ed.* Tincture of Senna and Jalap.

“Take of Senna *three ounces*; Jalap, in powder, *an ounce*; Coriander [seeds] bruised, Caraway [seeds] bruised, each, *half an ounce*; Cardamom [seeds] bruised *two drachms*; Sugar [refined] *four ounces*; Diluted Alcohol *three pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by beating well together the Senna,

Jalap, and Aromatics, moistening them thoroughly with Diluted Alcohol, allowing them to stand for forty-eight hours, then transferring them to an apparatus for displacement, and gradually pouring upon them Diluted Alcohol until three pints of filtered liquor are obtained." *U. S.*

"Take of Sugar *two ounces and a half*; Coriander, bruised, *one ounce*; Jalap, in moderately fine powder, *six drachms*; Senna *four ounces*; Caraway, bruised, and Cardamom seeds, bruised, of each, *five drachms*; Raisins, bruised, *four ounces*; Proof Spirit *two pints* [Imperial measure]. Digest for seven days, strain the liquor, express strongly the residuum, and filter the liquids. This tincture may be more conveniently and expeditiously prepared by percolation, as directed for the compound tincture of cardamom." *Ed.*

This is another form of the *elixir salutis*, and scarcely differs from the preceding in virtues. It is given for the same purposes, and in the same doses. W.

TINCTURA SERPENTARIÆ. *U. S., Lond., Ed., Dub. Tincture of Virginia Snakeroot.*

"Take of Virginia Snakeroot, bruised, *three ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Virginia Snakeroot, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours; then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

The *London College* takes *three ounces and a half* of the root, and *two pints* [Imperial measure] of proof spirit, and macerates for fourteen days; the *Dublin*, *three ounces* of the former and *two pints* of the latter, and macerates for seven days; the *Edinburgh*, *three ounces and a half* of the root, in moderately fine powder, *a drachm* of bruised cochineal, and *two pints* [Imp. meas.] of proof spirit, and proceeds either by percolation or digestion as for the tincture of Peruvian bark.

This tincture possesses the tonic and cordial properties of the root, and may be advantageously added to the infusion of Peruvian bark in low states of the system. The dose is one or two fluidrachms. W.

TINCTURA STRAMONII. *U. S. Tincture of Stramonium.*

"Take of Stramonium Seed, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

"This Tincture may also be prepared by thoroughly moistening the Stramonium Seed, in powder, with Diluted Alcohol, allowing it to stand for forty-eight hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained." *U. S.*

This tincture may be used for all the purposes for which stramonium is given, in the dose of from ten to twenty minims, repeated twice or thrice a day, and gradually increased till it obviously affects the system. W.

TINCTURA TOLUTANI. *U. S. TINCTURA TOLUTANA. Ed. TINCTURA BALSAMI TOLUTANI. Lond., Dub. Tincture of Tolu.*

"Take of Balsam of Tolu *three ounces*; Alcohol *two pints*. Macerate until the Balsam is dissolved; then filter through paper." *U. S.*

The *London College* employs *two ounces* of the balsam to *two pints* [Imperial measure] of rectified spirit; the *Edinburgh*, *three ounces and a half* of the balsam to *two pints* [Imp. meas.] of rectified spirit; the *Dublin*, *an ounce* to *a pint*.

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in chronic catarrhal affections; but the proportion of alcohol is too large to allow of its advantageous use in ordinary cases. The dose is one or two fluidrachms. In smaller quantities it is often employed to flavour cough mixtures. It is decomposed by water.

Off. Prep. Syrupus Tolutani, *U. S., Ed., Dub.*; Trochisci Morphix, *Ed.*; Trochisci Morphix et Ipecacuanhæ, *Ed.*; Trochisci Opii, *Ed.* W.

TINCTURA VALERIANÆ. *U. S., Lond., Ed., Dub.* *Tincture of Valerian.*

“Take of Valerian, bruised, *four ounces*; Diluted Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by thoroughly moistening the Valerian, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

The *London College* takes *five ounces* of bruised valerian, and *two pints* [Imperial measure] of proof spirit, and macerates for fourteen days; the *Dublin*, *four ounces* of the powdered root, and *two pints* of proof spirit, and macerates for seven days; the *Edinburgh*, *five ounces* of the former and *two pints* [Imp. meas.] of the latter, and proceeds by percolation or digestion as for the tincture of Peruvian bark.

This tincture possesses the properties of valerian, but cannot be given in ordinary cases, so as to produce the full effects of the root, without stimulating too highly in consequence of the large proportion of spirit. The dose is from one to four fluidrachms. W.

TINCTURA VALERIANÆ AMMONIATA. *U. S., Ed., Dub.*
TINCTURA VALERIANÆ COMPOSITA. *Lond.* *Ammoniated Tincture of Valerian.*

“Take of Valerian, bruised, *four ounces*; Aromatic Spirit of Ammonia *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by thoroughly moistening the Valerian, in powder, with Aromatic Spirit of Ammonia, allowing it to stand for twenty-four hours in a covered vessel, then transferring it to an apparatus for displacement, and gradually pouring upon it Aromatic Spirit of Ammonia until two pints of filtered liquor are obtained.” *U. S.*

“The *London College* takes *five ounces* of bruised valerian, and *two pints* [Imperial measure] of aromatic spirit of ammonia, and macerates for fourteen days; the *Dublin*, *two ounces* of the powdered root, and *a pint* of spirit of ammonia, and macerates for seven days; the *Edinburgh*, *five ounces* of valerian, and *two pints* [Imp. meas.] of spirit of ammonia, and proceeds either by percolation, or by digestion in a well-closed vessel, as directed for tincture of Peruvian bark.

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medical action. The tincture is employed as an antispasmodic in hysteria and other nervous affections. The dose is one or two fluidrachms, and should be given in sweetened water, milk, or some mucilaginous fluid. W.

TINCTURA ZINGIBERIS. *U. S., Lond., Ed., Dub.* *Tincture of Ginger.*

“Take of Ginger, bruised, *eight ounces*; Alcohol *two pints*. Macerate for fourteen days, express, and filter through paper.

“This Tincture may also be prepared by thoroughly moistening the Ginger, in powder, with Diluted Alcohol, allowing it to stand for twenty-four hours, then transferring it to an apparatus for displacement, and gradually pouring upon it Diluted Alcohol until two pints of filtered liquor are obtained.” *U. S.*

The *London College* takes *two ounces and a half* of sliced ginger, and *two pints* [Imperial measure] of rectified spirit, and macerates for fourteen days; the *Dublin*, *two ounces and a half* of coarsely powdered ginger, and *two pints* of rectified spirit, and macerates for seven days; the *Edinburgh*, *two ounces and a half* of coarsely powdered ginger, and *two pints* [Imp. meas.] of rectified spirit, and proceeds either by percolation or digestion, as for tincture of Peruvian bark.

The tinctures of the British Colleges are too weak with ginger to be used advantageously for any other purpose than merely to impart flavour. We greatly prefer the process of the *U. S. Pharmacopœia*, which yields a preparation in which the virtues of the ginger are not completely swallowed up in the menstruum. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol, or proof spirit, is apt to be turbid. Alcohol or rectified spirit is, therefore, properly preferred. Good Jamaica ginger should be used.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures, in debilitated states of the alimentary canal. It is, however, in this country, chiefly used for the preparation of syrup of ginger, for which purpose it is necessary to employ the strong tincture of the *U. S. Pharmacopœia*.

Off. Prep. Syrupus Zingiberis, *U. S.*

W.

TROCHISCI.

Troches.

Troches or lozenges are small, dry, solid masses, usually of a flattened shape, consisting of powders incorporated with sugar and mucilage. They are designed to be held in the mouth, and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in very large quantities, and are destitute of any very disagreeable flavour. They are much more used, and more skilfully prepared, in Europe than in this country. Tragacanth, from the greater tenacity of its mucilage, is better suited to their formation than gum Arabic. The following directions for preparing them are taken from the *Dictionnaire des Drogues*. A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the extended mass is rendered uniform by a frame upon which the ends of the roller are placed. The upper surface is now covered with a thin layer of sugar and starch, and the mass is divided into small cakes of a particular shape by means of a punch. These cakes are placed upon paper, and having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in bottles. In this way lozenges may be prepared from almost any medicine which the physician may deem it advisable to administer in that form.

The following formula will serve as a guide. Take of citric acid, in powder, a drachm; refined sugar eight ounces; oil of lemons twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. A species of lozenge is made by uniting the aromatic essential oils with sugar alone; but their preparation belongs to the confectioner rather than to the apothecary. The London and Dublin Pharmacopœias have omitted troches altogether. W.

TROCHISCI ACACIÆ. *Ed. Troches of Gum Arabic.*

"Take of Gum Arabic *four ounces*; Starch *one ounce*; Pure Sugar *one pound*. Mix and pulverize them, and make them into a proper mass with rose-water for forming lozenges." *Ed.*

These are useful in allaying the irritation of the fauces which excites coughing, and may be employed at pleasure. W.

TROCHISCI ACIDI TARTARICI. *Ed. Troches of Tartaric Acid.*

"Take of Tartaric Acid *two drachms*; Pure Sugar *eight ounces*; Volatile Oil of Lemons *ten minims*. Pulverize the Sugar and Acid, add the Oil, mix them thoroughly, and with Mucilage beat them into a proper mass for making lozenges." *Ed.*

These may be used as an agreeable refrigerant and demulcent in slight colds and fevers; but in large quantities they are apt to derange the stomach. W.

TROCHISCI CRETÆ. *U.S., Ed. Troches of Chalk.*

"Take of Prepared Chalk *four ounces*; Gum Arabic, in powder, *an ounce*; Nutmeg, in powder, *a drachm*; Sugar, in powder, *six ounces*. Rub them together until they are intimately mixed; then with water form them into a mass, to be divided into troches, each weighing ten grains." *U.S.*

The *Edinburgh College* uses the same ingredients in the same proportion, and beats them with a little water into a proper mass for making lozenges.

These are used as a gently astringent antacid in diarrhœa. W.

TROCHISCI GLYCYRRHIZÆ. *Ed. Troches of Liquorice.*

"Take of Extract of Liquorice [Liquorice, U. S.], and Gum Arabic, of each, *six ounces*; Pure Sugar *one pound*. Dissolve them in a sufficiency of boiling water; and then concentrate the solution over the vapour-bath to a proper consistence for making lozenges." *Ed.*

These lozenges are useful in allaying cough, but have been superseded in great measure by refined liquorice. W.

TROCHISCI GLYCYRRHIZÆ ET OPII. *U.S. TROCHISCI OPII. Ed. Troches of Liquorice and Opium.*

"Take of Opium, in powder, *half an ounce*; Liquorice in powder, Sugar in powder, Gum Arabic in powder, each, *ten ounces*; Oil of Anise *two fluidrachms*. Mix the powders intimately; then add the Oil of Anise, and with water form them into a mass, to be divided into troches each weighing six grains." *U.S.*

"Take of Opium *two drachms*; Tincture of Tolu *half an ounce*; Pure Sugar, in fine powder, *six ounces*; Powder of Gum Arabic, and Extract of Liquorice [Liquorice, U. S.], of each, *five ounces*. Reduce the Opium to a fluid extract by formula [page 947 U. S. Dispensatory]; mix it intimately with the Liquorice previously reduced to the consistence of treacle; add the

Tincture; sprinkle the Gum and Sugar into the mixture, and beat it into a proper mass, which is to be divided into lozenges of ten grains." *Ed.*

The U. S. formula is more easy of execution than the Edinburgh, and affords a product probably not inferior. A preparation equivalent to the above is much used in Philadelphia under the name of *Wistar's cough lozenges*.

These troches are demulcent and anodyne, and are very useful in allaying cough when the state of the case admits the employment of opium, of which each of them, prepared according to the U. S. formula, contains about one-tenth of a grain. *W.*

TROCHISCI IPECACUANHÆ. U. S. *Troches of Ipecacuanha.*

"Take of Ipecacuanha, in powder, *half an ounce*; Sugar, in powder, *fourteen ounces*; Arrow-root, in powder, *four ounces*; Mucilage of Tragacanth *a sufficient quantity*. Mix the powders intimately, and with the Mucilage form them into a mass, to be divided into troches each weighing ten grains." *U. S.*

These are useful expectorant lozenges in catarrhal complaints. Each of them contains about one-quarter of a grain of ipecacuanha. *W.*

TROCHISCI LACTUCARII. *Ed. Troches of Lactucarium.*

"To be prepared with Lactucarium in the same proportion and in the same manner as the Opium Lozenge." *Ed.*

This is a very feeble preparation, and scarcely deserves the officinal rank which has been given to it. Each lozenge contains only between the fifth and sixth of a grain of lactucarium. *W.*

TROCHISCI MAGNESIÆ. U. S., *Ed. Troches of Magnesia.*

"Take of Magnesia *four ounces*; Sugar *a pound*; Nutmeg, in powder, *a drachm*; Mucilage of Tragacanth *a sufficient quantity*. Rub the Magnesia, Sugar, and Nutmeg together until they are thoroughly mixed; then with the Mucilage form them into a mass, to be divided into troches each weighing ten grains." *U. S.*

"Take of Carbonate of Magnesia *six ounces*; Pure Sugar *three ounces*; Nutmeg *one scruple*. Pulverize them, and with Mucilage of Tragacanth beat them into a proper mass for making lozenges." *Ed.*

These are useful in acidity of stomach, especially when attended with constipation. *W.*

TROCHISCI MENTHÆ PIPERITÆ. U. S. *Troches of Peppermint.*

"Take of Oil of Peppermint *a fluidrachm*; Sugar, in powder, *a pound*; Mucilage of Tragacanth *a sufficient quantity*. Rub the Oil of Peppermint with the Sugar until they are thoroughly mixed; then with the Mucilage form them into a mass, to be divided into troches each weighing ten grains." *U. S.*

Useful in slight gastric or intestinal pains, nausea, and flatulence; but employed more for their agreeable flavour than for their medicinal effects.

TROCHISCI MORPHIÆ. *Ed. Troches of Morphia.*

"Take of Muriate of Morphia *one scruple*; Tincture of Tolu *half an ounce*; Pure Sugar *twenty-five ounces*. Dissolve the Muriate of Morphia in a little hot water; mix it and the Tincture of Tolu with the Sugar; and with a sufficiency of Mucilage form a proper mass for making lozenges; each of which should weigh about fifteen grains." *Ed.*

Useful for alleviating cough, and for other purposes which are answered by minute doses of morphia, of the muriate of which each lozenge contains about one-fortieth of a grain. *W.*

TROCHISCI MORPHIÆ ET IPECACUANHÆ. *Ed. Troches of Morphia and Ipecacuanha.*

“Take of Muriate of Morphia *one scruple*; Ipecacuan, in fine powder, *one drachm*; Tincture of Tolu *half a fluidounce*; Pure Sugar *twenty-five ounces*. Dissolve the Muriate in a little hot water; mix it with the Tincture and the Ipecacuan and Sugar; and with a sufficiency of Mucilage beat the whole into a proper mass, which is to be divided into fifteen grain lozenges.” *Ed.*

Expectorant and anodyne, useful especially in allaying cough. Each lozenge contains about one-fortieth of a grain of muriate of morphia, and three times as much ipecacuanha. W.

TROCHISCI SODÆ BICARBONATIS. *Ed. Troches of Bicarbonate of Soda.*

“Take of Bicarbonate of Soda *one ounce*; Pure Sugar *three ounces*; Gum Arabic *half an ounce*. Pulverize them, and with Mucilage beat them into a proper mass for making lozenges.” *Ed.*

Antacid and antilithic, useful in heart-burn and uric acid gravel. W.

UNGUENTA.

Ointments.

These are fatty substances, softer than cerates, of a consistence resembling that of butter, and such that they may be readily applied to the skin by inunction. Many of them become rancid when long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. W.

UNGUENTUM ACIDI NITRICI. *Dub. Ointment of Nitric Acid.*

“Take of Olive Oil *a pound*; Prepared Lard *four ounces*; Nitric Acid *five and a half fluidrachms*. Melt the Oil and Lard together in a glass vessel, and when they begin to congeal, add the Acid, and stir the mixture constantly with a glass rod till it stiffens.” *Dub.*

The acid is partially decomposed, evolving binoxide of nitrogen, and giving oxygen to the fatty matter, which becomes yellow, and assumes a firm consistence upon cooling. A similar ointment, prepared with lard and nitric acid, was originally employed by Alyon, under whose name it is still known on the continent of Europe. It was formerly one of the Edinburgh officinals, but was discarded at the last revision of the Pharmacopœia. It was used as an application to syphilitic ulcers, and eruptive affections, particularly psora and the different forms of porrigo; but it has been superseded by the ointment of nitrate of mercury, which is more efficient. The present Dublin ointment possesses the same properties, and is used for the same purposes. W.

UNGUENTUM ACIDI SULPHURICI. *Dub. Ointment of Sulphuric Acid.*

“Take of Sulphuric Acid *a drachm*; Prepared Lard *an ounce*. Mix them.” *Dub.*

In this process the acid is partly converted into sulphurous acid which escapes, and a portion of the lard is charred. The ointment was a favourite application with Dr. Duncan, Sen., in scabies, and we have found it effectual in the same complaint; but it should be diluted with an equal weight of

lard. Thus diluted, it may also be used with advantage in other eruptive affections, particularly ringworm; and still weaker, has been used in rheumatism and neuralgia. W.

UNGUENTUM ANTIMONII. U.S. UNGUENTUM ANTIMONIALE. *Ed.* UNGUENTUM ANTIMONII POTASSIO-TARTRATIS. *Lond.* UNGUENTUM TARTARI EMETICI. *Dub.* *Antimonial Ointment. Tartar Emetic Ointment.*

"Take of Tartrate of Antimony and Potassa, in very fine powder, *two drachms*; Lard *an ounce*. Mix them." U.S.

The *London* and *Edinburgh Colleges* mix *an ounce* of tartar emetic and *four ounces* of lard; the *Dublin*, a *drachm* of the former and *an ounce* of the latter.

This may be more conveniently prepared with *simple ointment*, as lard is too soft to be spread on linen, and simple ointment is sufficiently so to be applied by inunction.

The peculiar eruptive effect of tartar emetic may be procured in various ways, either by means of a strong solution, or of the powder sprinkled upon the surface of some adhesive plaster, or of the ointment as above directed. The last method is, perhaps, the most convenient, and most generally resorted to. The proportion of tartar emetic may vary from one drachm with the ounce of lard, as in the *Dublin* formula, to two drachms, as in the other officinal formulæ, or even to three drachms when a speedy effect is required, or the skin is not very susceptible to its action. A small portion of the ointment may be rubbed twice a day, or more frequently, upon the surface to be affected, or it may be applied spread upon a piece of linen. Care should be taken that the cuticle be entire, and that the application be not too long continued, as otherwise very severe inflammation, and even gangrenous ulceration, may result. We have, however, in some instances of great urgency, applied the ointment to a surface recently scarified in the operation of cupping; but under such circumstances, it should be used with much caution. W.

UNGUENTUM AQUÆ ROSÆ. U.S. *Ointment of Rose Water.*

"Take of Rose Water, Oil of Almonds, each, *two fluidounces*; Spermaceti *half an ounce*; White Wax *a drachm*. Melt together, by means of a water-bath, the Oil, Spermaceti, and Wax; then add the Rose Water, and stir the mixture constantly until it is cold." U.S.

This preparation is much employed under the name of *cold cream*. It is a white, very soft, and elegant unguent, deriving a grateful odour from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. It is a pleasant, cooling application to irritated and excoriated surfaces; and may be used with great advantage for chapped lips and hands, so frequent in cold weather. W.

UNGUENTUM CANTHARIDIS. U.S., *Lond.*, *Dub.* UNGUENTUM INFUSI CANTHARIDIS. *Ed.* *Ointment of Spanish Flies.*

"Take of Spanish Flies, in powder [very fine powder, *Dub.*], *two ounces*; Distilled Water *half a pint*; Resin Cerate *eight ounces*. Boil down the Water with the Spanish Flies to one-half, and strain; then mix the Cerate with the strained liquor, and evaporate to the proper consistence." U.S., *Dub.*

The *London College* takes *an ounce* of the flies, in very fine powder,

four fluidounces of distilled water, and four ounces of resin cerate, and proceeds as above.

“Take of Cantharides, in moderately fine powder, Resin, and Bees'-wax, of each, *one ounce*; Venice Turpentine, and Axunge [Lard], of each, *two ounces*; Boiling Water *five fluidounces*. Infuse the Cantharides in the Water for one night, squeeze strongly, and filter the expressed liquid. Add the Axunge, and boil till the water is dispersed. Then add the Wax and Resin; and when these have become liquid, remove the vessel from the fire, add the Turpentine, and mix the whole thoroughly.” *Ed.*

By these processes, the active matter of the flies is more uniformly diffused through the ointment, than when they are directly incorporated, in the state of powder, with the other ingredients. The preparation is thus better calculated to meet the end proposed of maintaining the discharge from blistered surfaces, without producing undue irritation. It has been said that the virtues of the flies are impaired by the boiling; but experience has proved the contrary. The Edinburgh College, by ordering merely an infusion of the flies, and a subsequent boiling down of the filtered infusion, loses any advantage which decoction may have in extracting the virtues of the flies, without avoiding whatever disadvantage may accrue from the heat. It is necessary, in the U.S., London, and Dublin processes, after the strained decoction and cerate have been mixed, to stir constantly during the continuance of the evaporation, in order to prevent the former from sinking to the bottom. It should be recollected, that this ointment is intended as a dressing for blisters, not to produce vesication. The Edinburgh ointment differs from the others in containing Venice turpentine, which renders it more stimulating. Dupuytren employed, as a local application to prevent the loss of hair, an ointment made by macerating a drachm of flies in a fluidounce of alcohol, and incorporating one part of the tincture thus formed with nine parts of lard. W.

UNGUENTUM CANTHARIDIS. *Ed.* CERATUM CANTHARIDIS. *Lond.* *Ointment of the Powder of Spanish Flies.*

“Take of Resinous Ointment *seven ounces*; Cantharides, in very fine powder, *one ounce*. Melt the Ointment; sprinkle into it the Cantharides powder, and stir the mixture briskly as it concretes on cooling.” *Ed.*

“Take of Spanish Flies, in very fine powder, *an ounce*; Spermaceti Cerate *six ounces*. To the Cerate softened by heat, add the Flies, and mix.” *Lond.*

This ointment, like the two preceding, is intended as a dressing for blistered surfaces, with a view to maintain the discharge. The flies should be very finely powdered, in order that they may be diffused as uniformly as possible through the mass. It is unfortunate that the term *ceratum cantharidis* has been conferred upon this preparation by the London College, as the same name is properly employed in the U.S. Pharmacopœia to express the preparation of flies intended to be used as a vesicatory. None of these ointments can be used in individuals liable to strangury from the external application of cantharides. W.

UNGUENTUM CETACEI. *Lond.* *Spermaceti Ointment.*

“Take of Spermaceti *six drachms*; White Wax *two drachms*; Olive Oil *three fluidounces*. Melt them together over a slow fire, and stir them constantly until cold.” *Lond.*

This ointment is employed as a mild dressing for blisters, wounds, and excoriated surfaces. It should be made in small quantities at a time, as it is apt to become rancid when long kept. W.

UNGUENTUM COCCULI. *Ed. Ointment of Cocculus Indicus.*

"Take *any convenient quantity* of Cocculus Indicus, separate and preserve the kernels, beat them well in a mortar, first alone and then with a little Axunge [Lard]; and then add Axunge till it amounts altogether to five times the weight of the kernels." *Ed.*

This ointment is used for the destruction of vermin, and in the cure of scabies and ringworm of the scalp. In the latter complaint it was found very useful by the late Dr. Hamilton, Sen., of Edinburgh. W.

UNGUENTUM CONII. *Dub. Ointment of Hemlock.*

"Take of fresh Hemlock Leaves, Prepared Lard, each, *two pounds*. Boil the Leaves in the Lard till they become crisp, and then express through linen." *Dub.*

This ointment has been used as an anodyne application to irritable piles, painful glandular swellings and scirrhus tumours, and to cancerous and other painful ulcers; but there is reason to believe that the virtues of the hemlock are impaired by the heat necessary in its preparation. An ointment prepared by mixing good extract of hemlock with lard would probably be more efficient. W.

UNGUENTUM CREASOTI. *U. S., Lond., Ed. Ointment of Creasote.*

"Take of Creasote *half a fluidrachm*; Lard *an ounce*. Add the Creasote to the Lard previously melted with a moderate heat, and stir them constantly till they are cold." *U. S.*

The *London College* mixes *half a fluidrachm* of creasote and *an ounce* of lard. The *Edinburgh College* takes *a drachm* of creasote and *three ounces* of lard, and proceeds as above directed.

For the use of this ointment see *Creasoton*, in the first part of this work. It may sometimes be advantageously diluted with lard when found to irritate. W.

UNGUENTUM CUPRI SUBACETATIS. *U. S., Dub. Unguentum ÆRUGINIS. Ed. Ointment of Subacetate of Copper.*

"Take of Subacetate of Copper, in fine powder, *a drachm*; Simple Ointment *fifteen drachms*. Add the Subacetate of Copper to the Ointment previously melted with a moderate heat, and stir them constantly till they are cold." *U. S.*

"Take of Resinous Ointment *fifteen ounces*; Verdigris, in fine powder, *one ounce*. Melt the Ointment, sprinkle into it the powder of Verdigris, and stir the mixture briskly as it cools and concretes." *Ed.*

"Take of Prepared Subacetate of Copper *half an ounce*; Olive Oil *an ounce*; Ointment of White Resin [resin cerate] *a pound*. Rub the Subacetate with the Oil; then add them to the Ointment previously melted, and mix." *Dub.*

This ointment is employed as a mild escharotic in fungous granulations, and, more or less diluted with lard, as a stimulating application to foul and flabby ulcers, scrofulous ulcerations of the edges of the eyelids, disease of the external meatus of the ear with purulent discharge, to warts and corns, and to certain cutaneous eruptions, particularly that form of porrigo denominated *ringworm of the scalp*. W.

UNGUENTUM ELEMI. *Lond., Dub. Ointment of Elemi.*

"Take of Elemi *a pound*; Common Turpentine *ten ounces*; Suet *two pounds*; Olive Oil *two fluidounces*. Melt the Elemi with the Suet, and

having removed them from the fire, immediately mix with them the Turpentine and Oil, and express through linen." *Lond.*

"Take of Resin of Elemi *a pound*; White Wax *half a pound*; Prepared Lard *four pounds*. Make an ointment, and strain it through a sieve while hot." *Dub.*

This ointment is applied as a gentle stimulant to weak ulcers, and may be used for maintaining the discharge of issues and setons. It is the *linimentum arcæi* of the older pharmacy. *W.*

UNGUENTUM GALLÆ. *U.S.* UNGUENTUM GALLARUM. *Dub.* *Ointment of Galls.*

"Take of Galls, in powder [very fine powder, *Dub.*], *an ounce*; Lard *seven ounces* [*eight ounces, Dub.*]. Mix them." *U.S., Dub.*

This is used chiefly in piles and prolapsus ani, though it may also be advantageously applied to flabby and indolent ulcers. *W.*

UNGUENTUM GALLÆ COMPOSITUM. *Lond.* UNGUENTUM GALLÆ ET OPII. *Ed.* *Compound Ointment of Galls.*

"Take of Galls, in very fine powder, *two drachms*; Lard *two ounces*; Hard Opium, in powder, *half a drachm*. Mix them." *Lond.*

The *Edinburgh College* takes *two drachms* of galls, *a drachm* of opium, and *an ounce* of lard, and rubs them together into a uniform mass.

This combination of galls and opium is sometimes employed, preferably to the simple gall ointment, in cases of irritable piles. From half a drachm to a drachm of camphor is sometimes added to the London ointment. *W.*

UNGUENTUM HYDRARGYRI. *U.S., Ed., Dub.* UNGUENTUM HYDRARGYRI FORTIUS. *Lond.* *Mercurial Ointment. Strong Mercurial Ointment.*

"Take of Mercury *two pounds*; Lard *twenty-three ounces*; Suet *an ounce*. Rub the Mercury with the Suet and a small portion of the Lard until the globules disappear; then add the remainder of the Lard, and mix." *U.S., Lond.*

"Take of Mercury *two pounds*; Axunge [Lard] *twenty-three ounces*; Suet *one ounce*. Triturate the Mercury with the Suet and a little of the Axunge till globules are no longer visible; then add the rest of the Axunge, and mix the whole thoroughly. This ointment is not well prepared so long as metallic globules may be seen in it with a magnifier of four powers. The Mercurial Ointment with the proportions here directed may be diluted at pleasure with twice or thrice its weight of axunge." *Ed.*

"Take of Purified Mercury, prepared Lard, *equal weights*. Rub them together in a marble or iron mortar, till the globules of mercury disappear." *Dub.*

Off. Prep. Ceratum Hydrargyri Compositum, *Lond.*; Linimentum Hydrargyri Comp., *Lond.*; Unguentum Hydrargyri Mitius. *Lond.*

UNGUENTUM HYDRARGYRI MITIUS. *Lond., Dub.* *Mild Mercurial Ointment.*

"Take of Strong Mercurial Ointment *a pound*; Lard *two pounds*. Mix them." *Lond.*

The *Dublin College* prepares this ointment with twice the quantity of lard used in the preparation of the stronger ointment.

The *U.S. Pharmacopœia* directs only one mercurial ointment, which accords in strength with the strongest ointment of the London and Dublin Colleges, containing equal weights of mercury and fatty matter. When the

physician wishes a weaker preparation, he may direct the ointment to be diluted with such a proportion of lard as may answer his purposes. The Edinburgh College, in allowing dilution of the ointment in certain fixed proportions, should have given names, by which these weaker preparations might be designated. The milder ointment of the London College contains one part of mercury to five of fat, that of the Dublin College, one of the former to two of the latter. If the apothecary keeps a milder preparation in his shop, it should be that of the London College, which, from the smaller proportion of mercury, is preferable to that of the Dublin College for the purposes to which the milder ointment is usually applied. It should always be understood that the stronger ointment is intended by the physician, unless the contrary is expressly stated.

In the preparation of mercurial ointment, care is requisite that the mercury should be completely extinguished. The trituration is best performed in a marble mortar, as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished, when a portion of the mass, rubbed upon paper or the back of the hand, exhibits no metallic globules under a magnifying glass of four powers. The operation cannot be considered as satisfactorily accomplished when the globules are invisible merely to the naked eye. To facilitate the process, which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. Turpentine and sulphur have been employed for this purpose, but are both inadmissible, the former because it renders the ointment too irritating, the latter because it forms with the mercury an inactive sulphuret. Their presence in the ointment may be detected by the peculiar odour which they respectively emit when exposed to heat. Sulphur, moreover, gives the ointment a darker colour than it has when pure. Rancidity in the lard employed also facilitates the extinguishment of the mercury, but is liable to the same objection as turpentine. M. Guibourt recommends the addition of one-sixteenth of old mercurial ointment, which experience has shown to be very useful in promoting the thorough mixture of the mercury and lard. M. Simonin recommends the use of lard which has been exposed in thin layers to a damp air for fifteen days. This facilitates the extinguishment of the metal; but it may be doubted whether it does not render the preparation more irritant by the chemical alteration of the lard. The following plan of preparing the ointment has been proposed by M. Chevallier. Having taken a pound of mercury and the same quantity of fresh lard, he introduces the metal with half the lard previously melted into a stone or glass bottle, shakes the mixture till it acquires the consistence of very thick syrup, then pours it into a mortar, and adds the remainder of the lard, stirring constantly. In this manner, according to Chevallier, a perfect ointment may be made in half an hour. But when prepared with lard alone, the ointment is apt, in hot weather, to become so soft as to allow the metal to separate. Hence the addition of suet in the processes of the U. S., London, and Edinburgh Pharmacopœias; and even a larger proportion might be employed when the ointment is prepared for use in the summer season.

Upon the whole, it may be considered doubtful whether any of the expedients for saving labour and time in the preparation of the ointment are wholly unobjectionable. Dr. Christison states that the better plan is not to complete the process by a continuous trituration, but to operate for a short time every day, and allow the ointment in the mean time to be exposed to the air. But so much labour is required in the process, that the

ointment is preferably made by machinery on the large scale. The fatty matters, kept in the fluid state by a temperature of about 100° , are triturated with the metal by means of two iron balls, which are driven rapidly round in a circular iron trough by means of steam power. The extinguishment of the mercury is thus effected in about twelve hours.

Mercurial ointment has when newly prepared a bluish colour, which becomes darker by age. It was formerly thought to contain the mercury in the state of protoxide; but it has been shown that most of the metal can be separated from the lard by methods not calculated to reduce the oxide; and chemists now generally admit that by far the greater portion of it exists in the preparation in a state of minute division, not of chemical combination. It is probable, however, that the metal is partially oxidized; and the darker colour which the ointment acquires by age is attributable to the further oxidation of the mercury. If the ointment be kept long in a melted state in a narrow vessel, metallic mercury subsides, and an oily liquid floats upon the surface. After this has been filtered so as to separate every thing undissolved, it is blackened by sulphuretted hydrogen, and yields oxide of mercury to acetic acid. Dr. Christison states that he has examined various samples of the ointment, and never failed to detect oxide of mercury; and he has inferred from his observations, that the oxide amounts to rather more than one per cent. (*Christison's Dispensatory*.) But the proportion is variable according to the age and mode of preparation of the ointment. It scarcely admits of a doubt that the oxide of mercury formed enters into chemical combination with the lard or one of its oily acids. Mr. Donovan advanced the idea that the medicinal activity of the ointment depended exclusively on this compound of the lard with the mercurial oxide. An ointment made by merely mixing lard and black oxide of mercury has not the same effect, because there is no chemical union between the ingredients. But, upon exposing such a mixture to a temperature of 350° , and continually agitating it for two hours, he found that every ounce of lard dissolved and combined with twenty-one grains of oxide, and the resulting compound was found to be equally effectual with the common ointment, and capable of being introduced into the system in one-third of the time. (*Paris's Pharmacologia*.) It has been proposed to substitute an ointment thus prepared for that made according to the officinal direction, as being more manageable, and of more uniform strength. Care, however, would be required in preparing it to avoid a temperature either too high or too low; as the former might decompose the oxide and the latter would be insufficient to effect its union with the lard. There would be danger also that the lard might be rendered irritant by the influence of the heat.

Mercurial ointment, when rubbed upon the surface of the body, produces, in consequence of its absorption, the same general effects upon the system as the other preparations of the metal. It is resorted to either alone, when circumstances prevent or discourage the internal use of mercury, or conjointly with the internal use of the medicine, to produce a more speedy or powerful effect in urgent cases. It may also be advantageously employed as a resolvent in local affections, as in the case of venereal buboes, and of chronic glandular swellings, upon which it may be made to operate directly by being applied in the course of the absorbents which pass through the enlarged glands. The proper quantity to be employed at one time, with a view to salivation, is about a drachm, which should be applied night and morning, by means of friction, to the inner surface of the thighs, legs, or arms, and continued till the system is affected.

In urgent cases, or in local affections, it may also be rubbed on other parts

of the body, or applied to blistered surfaces. The friction should on each occasion be continued till the whole of the ointment is absorbed. When frequently rubbed upon the same part, it is apt to produce a disagreeable eruption which interferes with its continued application. Camphor is sometimes added in order to render it more easy of absorption; but, without producing this effect, it increases the liability of the ointment to irritate the skin, and is of no other advantage than to soften its consistence, when too firm from a large proportion of suet.

Mercurial ointment has been employed, with some success, to prevent the maturation of the small pox pustule, and the consequent pitting. For this purpose it may be applied to the face or other part, thickly spread on patent lint or muslin, care being taken to prevent the access of the air to the covered part. To be successful it must be applied before the third or fourth day of the eruption; and the practitioner should always bear in mind the possible salivation which may result from its use, and regulate the extent of its application accordingly. The ointment has been recommended also in erysipelas and chilblains.

The weaker ointment is employed only as an application to ulcers, and to certain cutaneous eruptions. W.

UNGUENTUM HYDRARGYRI AMMONIATI. *U.S.* UNGUENTUM HYDRARGYRI AMMONIO-CHLORIDI. *Lond.* UNGUENTUM PRECIPITATI ALBI. *Ed.* UNGUENTUM HYDRARGYRI SUBMURIATIS AMMONIATI. *Dub.* *Ointment of Ammoniated Mercury. Ointment of White Precipitate.*

“Take of Ammoniated Mercury *a drachm*; Simple Ointment *an ounce and a half*. Add the Ammoniated Mercury to the Ointment previously softened over a gentle fire, and mix them.” *U. S.*

The processes of the *British Colleges* are essentially the same as the above.

This ointment is employed chiefly in cutaneous eruptions, such as psora, porrigo, and herpes. W.

UNGUENTUM HYDRARGYRI IODIDI. *Lond.* *Ointment of Iodide of Mercury.*

UNGUENTUM HYDRARGYRI BINIODIDI. *Lond.* *Ointment of Biniodide of Mercury.*

These two ointments are prepared by the *London College* from the iodide and biniodide of mercury, respectively, in the manner directed by the College for their ointment of nitric oxide of mercury. (See *Unguentum Hydrargyri Oxidi Rubri*.)

They are both employed as dressings to scrofulous ulcers, the ointment of the biniodide being preferred, on account of its much greater activity, when the ulcers are very indolent. W.

UNGUENTUM HYDRARGYRI NITRATIS. *U.S., Lond.* UNGUENTUM CITRINUM. *Ed.* UNGUENTUM HYDRARGYRI NITRATIS *vel* UNGUENTUM CITRINUM. *Dub.* *Ointment of Nitrate of Mercury. Citrine Ointment.*

“Take of Mercury *an ounce*; Nitric Acid *eleven fluidrachms*; fresh Neats-foot Oil *nine fluidounces*; Lard *three ounces*. Dissolve the Mercury in the Acid; then melt the Oil and Lard together, and when they begin to stiffen upon cooling, add the solution and mix.” *U. S.*

“Take of Mercury *an ounce*; Nitric Acid *eleven fluidrachms* [Imperial measure]; Lard *six ounces*; Olive Oil *four fluidounces* [Imp. measure].

First dissolve the Mercury in the Acid; then, while the solution is hot, mix it with the Lard and Oil previously melted together." *Lond.*

"Take of Purified Mercury *an ounce*; Nitric Acid *eleven drachms and a half*; Olive Oil *a pint*; Prepared Lard *four ounces*. Dissolve the Mercury in the Acid, then mix the solution with the Oil and Lard previously melted together, and form an ointment, in the manner directed for the Ointment of Nitric Acid." *Dub.*

"Take of Pure Nitric Acid *eight fluidounces and six fluidrachms* [Imperial measure]; Mercury *four ounces*; Axunge [lard] *fifteen ounces*; Olive Oil *thirty-two fluidounces*. Dissolve the Mercury in the Acid with the aid of a gentle heat. Melt the Axunge in the Oil with the aid of a moderate heat in a vessel capable of holding six times the quantity; and, while the mixture is hot, add the solution of mercury, also hot, and mix them thoroughly. If the mixture do not froth up, increase the heat a little till this take place. Keep this ointment in earthenware vessels, or in glass vessels secluded from the light." *Ed.* Dr. Christison in his Dispensatory states that, in this formula, in order to meet the intentions of its framers, the quantity of Olive Oil should be *thirty-eight fluidounces and a half*, and of Nitric Acid (sp. gr. from 1.380 to 1.390) *nine fluidounces and a half*.

The chemical changes which take place in the preparation of this ointment are not precisely known. They are somewhat different according to the circumstances under which the operation is performed; for example, according to the proportion and strength of the acid, the nature of the fatty matter, and the degree of heat employed. The mercury, in the first step of the process, is oxidized at the expense of a portion of the acid, nitrous fumes escape, and the undecomposed acid unites with the oxidized metal, forming nitrate of the deutoxide of mercury if heat be employed, and a mixture of this with nitrate of the protoxide, if the process be conducted at a low temperature. If the officinal formulæ are strictly complied with in relation to the strength of the acid, this will be in excess, and it is not improbable that a portion of nitrous or hyponitrous acid may at the same time exist in the mixture. When the mercurial solution is added to the fatty matter, a reaction takes place, which probably results in the production of the yellow subnitrate of the deutoxide of mercury, of one or more of the fatty acids, as the oleic, margaric, and stearic, and of elaidin or elaidic acid, or both. (See page 481.) It is also highly probable that portions of these fatty acids combine with the oxide of mercury. But the degree to which these changes take place is influenced greatly by the temperature to which the mixture is exposed. If this be low there is little or no escape of gas, if it be elevated, there is a copious evolution of nitrous fumes. In the former case the changes are obviously less considerable than in the latter.

As frequently prepared, this ointment, though at first beautifully yellow and of the proper consistence, soon begins to change, acquiring in time a dirty greenish and mottled colour, and becoming so hard and friable as to be unfit for use unless mixed with lard. These results have been ascribed to various causes, and as many different modifications of the process have been proposed in order to obviate them. Dr. A. T. Thomson considered the main defect of the British processes to be too large a proportion of lard; but it has been ascertained that a very good ointment may be made with lard as the only fatty ingredient. The U. S. process is based upon the fact that olive oil is hardened by nitrous acid or the nitrate of mercury, while the same effect is not produced upon neat's-foot oil. (See *Oleum Olivæ*,

page 493.) This process produces a good ointment, which, though it sometimes assumes a greenish colour on exposure, retains a soft unctuous consistence for a long time. We have in our possession specimens of ointment, prepared several years since according to the U.S. formula, which have at this time a uniform orange-yellow colour and a perfectly good unctuous consistence.* It is probable that other animal oils will answer the same purpose; and it is asserted that a good preparation may be made with lard or butter. The drying vegetable oils do not appear, like olive oil, to be converted by nitrous acid or the nitrate of mercury into elaidin, and it was a fair inference that they might be employed advantageously in the preparation of citrine ointment. Accordingly, Dr. Fessenden, of North Carolina, states, in his inaugural essay, that he substituted the linseed oil for the neats-foot oil of the U.S. process, and succeeded in obtaining a perfectly good and durable ointment. It is now stated that the want of success with many operators who have followed the British official processes, has been owing not to the character of the particular oil employed, but to deficiency of strength in the nitric acid, and the want of a due degree of heat. Mr. Alsop asserts that if the nitric acid be of the sp. gr. 1.5 as directed by the Colleges, or if the quantity of a weaker acid be increased so as to compensate for its deficiency in strength, and if the fatty matters be mixed with the mercurial solution at an elevated temperature, a permanently soft and golden-coloured ointment will result. (*Pharm. Transact.* Sept. 1841.) It is probable that the discoloration which is so apt to take place in the preparation is owing to the deoxidizing influence of the fatty matter upon the mercurial oxide. Now if by a sufficient excess of acid and an elevated temperature the fats be thoroughly oxidized during the process, they will have less affinity for oxygen afterwards, and consequently less ability to take it from the oxide of mercury. That they are oxidized at the expense either of the nitric acid or nitrate when heat is used, is proved by the abundant extrication of nitric oxide during the operation. The process of the Edinburgh College above given meets these requisites, and is said to yield an excellent ointment. The same process, before its adoption by the College, had been long employed by Mr. Duncan, a chemist and druggist of Edinburgh, who appears to have been the first to ascertain the advantage of heat in the preparation of the ointment.

In applying heat, according to the Edinburgh process, when the fatty matter and mercurial solution are mixed, care must be taken that it be not in excess. Gas is extricated at 180° , and at 212° escapes so abundantly that the mixture boils over unless the vessel be very large. (Alsop.) Besides, if the heat be too great, a portion of the mercury is reduced, and the colour of the ointment impaired. When large quantities of materials are operated upon, the reaction which occurs produces of itself a sufficient heat; but in ordinary cases the temperature should be kept at about 190° by means of a water-bath. It should always be sufficient to produce a copious extrication of gas. The ointment should be prepared in a glass, porcelain, or well-glazed earthen vessel; and a glass rod or wooden spatula should be employed for stirring the mixture.

Medical Uses. This ointment is much and very advantageously employed, as a stimulant and alterative application, in various forms of porriço, as

* See "Remarks on the preparation of Citrine Ointment, by W. R. Fisher," in the *Journal of the Philadelphia College of Pharmacy*, i. 171. It is said that the three ounces of lard directed in the U.S. formula may be advantageously dispensed with, and its place supplied by three additional fluidounces of the neats-foot oil. See the same *Journal*, iv. 197.

tinea capitis and crusta lactea, in psoriasis and pityriasis, in certain forms of herpes, in psorophthalmia and inflammation of the eye and eyelids connected with porrigo of the face or scalp, and in various other ulcerative and eruptive affections. It should be diluted with lard, unless in cases which require a very stimulant application. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied. W.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. U. S. UNGUENTUM HYDRARGYRI NITRICO-OXYDI. Lond. UNGUENTUM OXIDI HYDRARGYRI. Ed. UNGUENTUM HYDRARGYRI OXYDI NITRICI. Dub. *Ointment of Red Oxide of Mercury.*

"Take of Red Oxide of Mercury, in very fine powder, *an ounce*; Simple Ointment *eight ounces*. Add the Oxide of Mercury to the Ointment previously softened over a gentle fire, and mix them." U. S.

"Take of Nitric-oxide of Mercury *an ounce*; White Wax *two ounces*; Prepared Lard *six ounces*. To the Wax and Lard, melted together, add the Nitric Oxide of Mercury, in very fine powder, and mix." Lond., Dub.

"Take of Red Oxide of Mercury *one ounce*; Axunge [Lard] *eight ounces*. Triturate them into a uniform mass. Ed.

The U. S. Pharmacopœia contemplates the same red oxide of mercury as the British Colleges, that, namely, prepared from the nitrate, and usually called *red precipitate*. It is highly important that the oxide should be thoroughly pulverized before being mixed with the lard; as otherwise it might prove very injurious in cases of ophthalmia, in which it is sometimes used.

This ointment loses its fine red colour when long kept, probably in consequence of the conversion of the red oxide into the black. It is best to prepare it only in small quantities at a time. It is a highly useful stimulating ointment, much employed in indolent and foul ulcers, in porrigo of the scalp, psorophthalmia, and in chronic conjunctival ophthalmia, especially when attended with thickening of the inner membrane of the eyelids, or with specks upon the cornea. It may be diluted with lard if found too stimulating. W.

UNGUENTUM IODINI. U. S. UNGUENTUM IODINII. Dub. *Ointment of Iodine.*

"Take of Iodine *twenty grains*; Alcohol *twenty minims*; Lard *an ounce*. Rub the Iodine first with the Alcohol and then with the Lard until they are thoroughly mixed." U. S.

"Take of Iodine *a scruple*; Prepared Lard *an ounce*. Rub them together so as to form an ointment." Dub.

This ointment, when rubbed upon the skin, imparts to it an orange colour, which, however, slowly disappears with the evaporation of the iodine. It is useful as a local application in goitre, scrofulous swellings of the glands, and other chronic tumefactions, operating probably through the medium of absorption. When continued for some time, it occasionally produces a pustular eruption upon the portion of skin to which it is applied. Dr. Cerchiari strongly recommends it in cases of enlarged tonsils after the disappearance of inflammation. It should be applied to the tonsils morning and evening by means of a camel's hair pencil. In two months, according to the author, the enlargement disappears. (*Am. Journ. of Pharm.* viii. 83.) The ointment should be prepared only as wanted for use; for it undergoes change if kept, losing its deep-orange brown colour and becoming pale upon the surface. W.

UNGUENTUM IODINI COMPOSITUM. U. S. UNGUENTUM IODINII COMPOSITUM. *Lond.* UNGUENTUM IODINEI. *Ed.* *Compound Ointment of Iodine.*

"Take of Iodine *half a drachm*; Iodide of Potassium *a drachm*; Alcohol *a fluidrachm*; Lard *two ounces*. Rub the Iodine and Iodide of Potassium first with the Alcohol and then with the Lard until they are thoroughly mixed." *U. S.*

The *London* formula is the same as the above. The *Edinburgh College* directs *a drachm* of iodine and *two drachms* of the iodide of potassium to be rubbed together, *four ounces* of lard to be gradually added, and the trituration to be continued till a uniform ointment is obtained.

This preparation is employed for the same purposes as the preceding, from which it differs chiefly in being somewhat stronger with iodine; as the iodide of potassium adds little to its virtues, and the spirit is employed only to facilitate the admixture. W.

UNGUENTUM MEZEREI. U. S. *Ointment of Mezereon.*

"Take of Mezereon, sliced transversely, *four ounces*; Lard *fourteen ounces*; White Wax *two ounces*. Moisten the Mezereon with a little Alcohol, and beat it in an iron mortar until reduced to a fibrous mass; then digest it with the Lard, in a salt-water bath, for twelve hours, strain with strong expression, and allow the strained liquid to cool slowly, so that any undissolved matters may subside. From these separate the medicated Lard, melt it with the Wax at a moderate heat, and stir them constantly till they are cold." *U. S.*

This is equivalent to the *pommade épispastique au garou* of the French Codex, which is prepared from the bark of the *Daphne Gnidium*. The ointment may also be made, as proposed by Guibourt, by mixing two drachms of the alcoholic extract of mezereon with nine ounces of lard and one of wax. It is used as a stimulating application to blistered surfaces in order to maintain the discharge, and to obstinate, ill-conditioned, and indolent ulcers. W.

UNGUENTUM PICIS LIQUIDÆ. U. S., *Lond.*, *Ed.*, *Dub.* *Tar Ointment.*

"Take of Tar, Suet, each, *a pound*. Add the Tar to the Suet previously melted with a moderate heat, and stir them constantly till they are cold." *U. S.*

The *London* and *Dublin Colleges* melt together *equal parts* of the tar and suet, and strain the mixture, the former through linen, the latter through a sieve. The *Edinburgh College* takes *five ounces* of tar and *two ounces* of bees'-wax, and having melted the wax with a gentle heat, adds the tar, and stirs the mixture briskly while it concretes.

Tar ointment is highly useful as a stimulant application in various scaly and scabby eruptions, particularly in psoriasis, and in that form of porrigo usually called *tinea capitis* or scald head. In the last mentioned affection. it should be applied night and morning; and in bad cases the patient should constantly wear a cap thickly spread with the ointment upon its internal surface. W.

UNGUENTUM PICIS NIGRÆ. *Lond.* *Ointment of Black Pitch.*

"Take of Black Pitch, Wax, Resin, each, *nine ounces*; Olive Oil *sixteen fluidounces* [Imperial measure]. Melt them together, and strain through linen." *Lond.*

This is a stimulant ointment, applicable to the same purposes as the preceding. W.

UNGUENTUM PIPERIS NIGRI. *Dub. Ointment of Black Pepper.*

"Take of Prepared Lard *a pound*; Black Pepper, in powder, *four ounces*. Make an ointment." *Dub.*

This is highly irritating, and has been used as a remedy in tinea capitis, but is not now employed. W.

UNGUENTUM PLUMBI ACETATIS. *Ed., Dub. CERATUM PLUMBI ACETATIS. Lond. Ointment of Acetate of Lead.*

"Take of Simple Ointment *twenty ounces*; Acetate of Lead, in fine powder, *one ounce*. Mix them thoroughly." *Ed.*

The *London College* melts *two ounces* of white wax in *seven fluid-ounces* of olive oil; then adds gradually *two drachms* of acetate of lead previously rubbed with *a fluidounce* of olive oil; and stirs with a spatula till they are mixed. The *Dublin College* mixes *an ounce* of acetate of lead with *a pound and a half* of ointment of white wax.

This is an excellent ointment in burns, and other excoriated or ulcerated surfaces, particularly blisters in an inflamed state. W.

UNGUENTUM PLUMBI CARBONATIS. *U.S., Ed., Dub. Ointment of Carbonate of Lead.*

"Take of Carbonate of Lead, in very fine powder, *two ounces*; Simple Ointment *a pound*. Add the Carbonate of Lead to the Ointment previously softened over a gentle fire, and mix them." *U.S.*

The *Edinburgh College* prepares this ointment by mixing thoroughly *one ounce* of carbonate of lead with *five ounces* of simple ointment. The *Dublin College* employs the proportions of the *U.S. Pharmacopœia*.

This ointment is used for the same purposes as the preceding. W.

UNGUENTUM PLUMBI COMPOSITUM. *Lond. Compound Ointment of Lead.*

"Take of Prepared Chalk *eight ounces*; Distilled Vinegar *six fluid-ounces*; Lead Plaster *three pounds*; Olive Oil *a pint* [Imperial measure]. Dissolve the Plaster in the Oil with a slow fire, then gradually add the Chalk previously mixed with the Vinegar, the effervescence having subsided, and stir them constantly until they become cold." *Lond.*

Employed as a dressing for indolent ulcers. W.

UNGUENTUM PLUMBI IODIDI. *Lond. Ointment of Iodide of Lead.*

"Take of Iodide of Lead *an ounce*; Lard *eight ounces*. Rub and mix them." *Lond.*

Employed as a discutient in chronic glandular swellings, and enlargements of the joints. W.

UNGUENTUM POTASSÆ HYDRIODATIS. *Dub. Ointment of Hydriodate of Potassa.*

"Take of Hydriodate of Potassa [Iodide of Potassium] *a scruple*; Prepared Lard *an ounce*. Rub them together so as to form an ointment." *Dub.*

It is said that these ingredients incorporate better, if the iodide of potassium be first dissolved in its own weight of distilled water, and then mixed with the lard. (*Am. Journ. of Med. Sci. N. S. iii. 203.*)

This ointment is employed for the discussion of goitres, scrofulous tumours, and other indolent swellings; and is usually preferred to the oint-

ment of iodine, as it does not like that discolour the skin. It is probably, however, of inferior virtue, and certainly contains too small a proportion of the iodide. One drachm to the ounce of lard would not be too much, and may sometimes be exceeded.

W.

UNGUENTUM SAMBUCI. *Lond., Dub. Elder Ointment.*

"Take of Elder [flowers], Lard, each, *two pounds*. Boil the Elder Flowers in the Lard till they become crisp, then express through linen." *Lond.*

"Take of fresh Elder Leaves *three pounds*; Prepared Lard *four pounds*; Prepared Mutton Suet *two pounds*. Boil the leaves in the Lard till they become crisp; then strain with expression; lastly, add the Suet, and melt them together." *Dub.*

Elder flowers impart odour to lard without adding to its virtues. The Dublin ointment of the leaves has a green colour, and is popularly employed as a cooling application in England.

W.

UNGUENTUM SCROPHULARIÆ. *Dub. Ointment of Figwort.*

"Take of fresh Figwort Leaves, Prepared Lard, each, *two pounds*; Prepared Mutton Suet *a pound*. Boil the leaves in the fat till they become crisp, then strain with expression." *Dub.*

For the properties of this ointment, see *Scrophularia Nodosa*. W.

UNGUENTUM SIMPLEX. *U.S., Ed.* UNGUENTUM CERÆ ALBÆ. UNGUENTUM CERÆ FLAVÆ. *Dub. Simple Ointment.*

"Take of White Wax *a pound*; Lard *four pounds*. Melt them together with a moderate heat, and stir them constantly till they are cold." *U.S.*

The *Edinburgh College* orders *five fluidounces and a half* of olive oil, and *two ounces* of white wax. The *Dublin College* makes two preparations, one with white, the other with yellow wax, in each case mixing the wax with lard in the same proportion as directed in the *U.S. Pharmacopœia*.

This is a useful emollient ointment, occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle for the application of more active substances. It is the basis of several official ointments.

Off. Prep. Unguentum Cupri Subacetatis, *U.S.*; Unguent. Hydrargyri Ammoniatum, *U.S.*; Unguent. Hydrarg. Oxidi Rubri, *U.S.*; Unguent. Plumbi Acetatis, *Ed.*; Unguent. Plumbi Carbonatis, *U.S., Ed.* W.

UNGUENTUM STRAMONII. *U.S. Ointment of Stramonium.*

"Take of fresh Stramonium Leaves, cut into pieces, *a pound*; Lard *three pounds*; Yellow Wax *half a pound*. Boil the Stramonium Leaves in the Lard, until they become friable; then strain through linen. Lastly, add the Wax previously melted, and stir them until they are cold." *U.S.*

Fresh narcotic vegetables yield their active principles, and chlorophylle or green colouring matter, to oleaginous substances, when heated with them; and several official ointments besides the present are prepared in this manner. In the pharmacy of the continent of Europe, olive oil is frequently employed as the solvent; and the resulting preparations are called *olea infusa*. Several of these are ordered by the French Codex, as the oils of henbane, stramonium, tobacco, &c. Lard is preferred in British and American pharmacy, as affording preparations of a more convenient consistence. The boiling takes place at a lower temperature than that necessary for the evaporation of the lard or oil, and is owing to the escape of the watery parts of

the plants. It should be continued till all the water is driven off; as this, if allowed to remain, would render the ointment more liable to spontaneous decomposition; and, besides, the colouring matter of the narcotic is not freely extracted till after the dissipation of the water.

The ointment of stramonium is a useful anodyne application in irritable ulcers, in painful hemorrhoids, and in some cutaneous eruptions. W.

UNGUENTUM SULPHURIS. *U.S., Lond., Ed., Dub. Sulphur Ointment.*

“Take of Sulphur *a pound*; Lard *two pounds*. Mix them.” *U.S.*

The *London College* employs *three ounces* of sulphur, *half a pound* of lard, and *twenty minims* of oil of bergamot; the *Edinburgh*, *four ounces* of lard and *one ounce* of sublimed sulphur; and the *Dublin*, *four pounds* of prepared lard and *a pound* of sublimed sulphur.

Sulphur ointment is a specific for the itch. It should be applied every night till the complaint is cured; and it is recommended that only one-fourth of the body should be covered at a time. We have usually directed it to be applied over the whole surface, and have found no inconvenience to result. Four applications are usually sufficient to effect a cure. It is thought by some that powdered roll sulphur is more efficacious than the sublimed. Sulphur ointment, applied freely over the variolous eruption, in its early stage, is said to prevent the maturation of the pustules and consequent pitting. (See *Am. Journ. of Med. Sci. N. S.* ii. 196.) The disagreeable odour of the ointment may be in some measure concealed by a little oil of lemons, or oil of bergamot as in the *London* preparation. W.

UNGUENTUM SULPHURIS COMPOSITUM. *U.S., Lond. Compound Sulphur Ointment.*

“Take of Sulphur *an ounce*; Ammoniated Mercury, Benzoic Acid, each, *a drachm*; Oil of Bergamot, Sulphuric Acid, each, *a fluidrachm*; Nitrate of Potassa *two drachms*; Lard *half a pound*. To the Lard, previously melted with a moderate heat, add the other ingredients, and stir them constantly till they are cold.” *U.S.*

This ointment is essentially different from that which is directed, under the same name, by the *London College*. Though, perhaps, not more efficient than the simple sulphur ointment in the cure of itch, it has a less unpleasant smell, and may be advantageously applied to the cure of other eruptive affections, such as *tinea capitis* and *crusta lactea*.

“Take of Sulphur *half a pound*; White Hellebore, in powder, *two ounces*; Nitrate of Potassa *a drachm*; Soft Soap *half a pound*; Lard *a pound and a half*; Oil of Bergamot *thirty minims*. Mix them.” *Lond.*

This is thought to be more efficacious than the simple sulphur ointment; but the white hellebore renders it also more irritating. W.

UNGUENTUM TABACI. *U.S. Tobacco Ointment.*

“Take of fresh Tobacco, cut in pieces, *an ounce*; Lard *a pound*. Boil the Tobacco in the Lard over a gentle fire till it becomes friable; then strain through linen.” *U.S.*

In the first edition of the *U. S. Pharmacopœia*, this ointment, under the name of “Tobacco Liniment,” was directed to be prepared with common dried tobacco; but in this condition the leaves do not yield their virtues to lard. The error was corrected in the second edition. Though the tobacco plant is not an object of general culture in the Northern States, it may readily be produced in gardens, in quantities sufficient to supply any demand for the fresh leaves which can possibly arise. The remarks made

under the head of *Unguentum Stramonii*, in relation to the preparation of ointments from the fresh narcotics, are applicable in this instance.

Tobacco ointment is useful in irritable ulcers, and various cutaneous eruptions, particularly *tinea capitis*; but great care must be taken, especially in children, not to employ it in such quantities as to endanger the production of the constitutional effects of the narcotic. W.

UNGUENTUM VERATRI ALBI. U. S. UNGUENTUM VERATRI. *Lond., Dub. Ointment of White Hellebore.*

"Take of White Hellebore [root], in powder, *two ounces*; Oil of Lemons *twenty minims*; Lard *eight ounces*. Mix them." U. S., *Lond.*

The *Dublin College* employs the same proportion of white hellebore and lard, but omits the oil of lemons.

This ointment is sometimes employed with advantage in the itch. It is less disagreeable, but also less certain than the sulphur ointment. It should be employed with caution in children. W.

UNGUENTUM ZINCI OXIDI. U. S. UNGUENTUM ZINCI. *Lond., Ed. UNGUENTUM ZINCI OXYDI. Dub. Ointment of Oxide of Zinc.*

"Take of Oxide of Zinc *an ounce*; Lard *six ounces*. Mix them." U. S., *Lond.*

The *Edinburgh College* employs *six ounces* of simple liniment, and *one ounce* of oxide of zinc; the *Dublin*, a *pound* of ointment of white wax (simple ointment), and *two ounces* of the prepared oxide. By the latter the ointment is melted before the addition of the oxide.

The oxide of zinc directed in the U. S., London, and Edinburgh Pharmacopœias, is that obtained by precipitation and ignition, and, being in the state of fine powder, requires no previous preparation. That employed by the *Dublin College*, being procured by the combustion of the metal, requires to be levigated before it can be used for the formation of the ointment.

This preparation is employed as a mild astringent application in chronic ophthalmia with a relaxed state of the vessels, in various cutaneous eruptions, and in sore nipples and other instances of excoriation or ulceration. It has taken the place of the old and discarded *unguentum tutiæ*, or *tutty ointment*, prepared from tutty or the impure oxide of zinc, by mixing it with five parts of simple ointment. W.

VERATRIA.

Veratria.

VERATRIA. U. S., *Lond., Ed. Veratria.*

"Take of Cevadilla, bruised, *two pounds*; Alcohol *three gallons*; Diluted Sulphuric Acid, Solution of Ammonia, Purified Animal Charcoal, Magnesia, each, *a sufficient quantity*. Boil the Cevadilla in a gallon of the Alcohol, in a retort with a receiver attached, for an hour, and pour off the liquor. To the residue add another gallon of the Alcohol, together with the portion recently distilled, again boil for an hour, and pour off the liquor. Repeat the boiling a third time with the remaining Alcohol, and with that distilled in the previous operation. Press the Cevadilla, mix and strain the liquors, and by means of a water-bath distil off the Alcohol. Boil the residue three or four times in water acidulated with Sulphuric Acid, mix and strain the liquors, and evaporate to the consistence of syrup. Add Magnesia in slight excess, shake the mixture frequently, then express,

and wash what remains. Repeat the expression and washing two or three times, and, having dried the residue, digest it with a gentle heat several times in Alcohol, and strain after each digestion. Distil off the Alcohol from the mixed liquors, boil the residue for fifteen minutes in water with a little Sulphuric Acid and Purified Animal Charcoal, and strain. Having thoroughly washed what remains, mix the washings with the strained liquor, evaporate with a moderate heat to the consistence of syrup, and then drop in as much Solution of Ammonia, as may be necessary to precipitate the veratria. Lastly, separate and dry the precipitate." *U. S.*

The *London* process is, in all essential points, the same as the above, of which it was the original.

"Take any convenient quantity of Cevadilla; pour boiling water over it in a covered vessel, and let it macerate for twenty-four hours; remove the Cevadilla, squeeze it, and dry it thoroughly with a gentle heat. Beat it now in a mortar, and separate the seeds from the capsules by a brisk agitation in a deep narrow vessel. Grind the seeds in a coffee-mill, and form them into a thick paste with Rectified Spirit. Pack this firmly in a percolator, and pass Rectified Spirit through it till the Spirit ceases to be coloured. Concentrate the spirituous solutions by distillation so long as no deposit forms; and pour the residuum while hot into twelve times its volume of cold water. Filter through calico, and wash the residuum on the filter so long as the washings precipitate with ammonia. Unite the filtered liquid with the washings, and add an excess of ammonia. Collect the precipitate on a filter, wash it slightly with cold water, and dry it first by imbibition with filtering paper, and then in the vapour-bath. A small additional quantity may be got by concentrating the filtered ammoniacal fluid and allowing it to cool." *Ed.*

In the *U. S.* and *London* process the first step is to obtain a tincture of cevadilla. In the *Edinburgh* process, the use of alcohol is preceded by measures calculated to bring the seeds into a proper state for its action. This is not satisfactorily effected by mere bruising. The seeds are not thus separated from the capsules; and, on account of their elasticity, they cannot be conveniently comminuted in a mortar. The mode of proceeding given in the *Edinburgh Pharmacopœia* was suggested by Christison, and is said by him to answer the purpose. In the *U. S.* process, the tincture, when made, is evaporated to the consistence of an extract. This contains the veratria combined with some vegetable acid as it exists in the seeds. From the extract the alkali is dissolved by the acidulated water, which at the same time converts it in great measure into a sulphate, a small portion possibly remaining in the solution combined with an excess of the native acid. The magnesia combines with the acids and throws down the veratria, which is then taken up by alcohol, and again yielded in a purer state by evaporation. To purify it still further, it is redissolved in water by the agency of sulphuric acid, is submitted to the action of animal charcoal, and is finally precipitated by ammonia. In the *Edinburgh* process, the tincture is concentrated until it begins to let fall a precipitate, and is then poured into water, which throws down the resin and oil with a portion of the colouring matter, and retains the salt of veratria. This is then decomposed by ammonia, and the precipitated veratria is slightly washed with cold water to free it from adhering impurities. If much water is employed in the washing, a considerable portion of the veratria is lost, in consequence of being in some degree soluble in that menstruum in its ordinary impure state.

Obtained by either of the above processes veratria is not entirely pure, though sufficiently so for medical use. It is a grayish or brownish-white

powder, without odour, and of a bitter, acrid taste, producing a sense of tingling or numbness in the tongue, and exciting violent sneezing and coryza when admitted into the nostrils. For the properties of the pure alkali the reader is referred to page 610. The composition of veratria is expressed, according to Couerbe, by the formula $C_{34}H_{22}O_6N$. It may be recognised by its sensible properties, incapability of being crystallized, combustibility, fusibility, peculiar solubilities (see page 610), alkaline reaction, the intense red colour it assumes upon contact with concentrated sulphuric acid, the yellow solution it forms with nitric acid, and the white precipitates which its solution in dilute acetic acid yields with ammonia and the infusion of galls. (*Pereira's Mat. Med.*) It may be used either in the uncombined state or united with acids; as in both forms it produces essentially the same effects.

Medical Properties and Uses. Veratria is a powerful irritant, capable of producing inflammation in the parts to which it is applied, and extending a peculiar action to the nervous system. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling, which, when the application is continued for a considerable length of time, extends, according to Turnbull, over the whole surface of the body. Sometimes an evanescent blush is produced, and still more rarely an eruption upon the skin, but, according to the same author, no marks of inflammation are in general evinced. Upon the denuded cutis, however, veratria and its salts are powerfully irritating; so much so as to prevent their advantageous application in this way. In the mouth and fauces they produce an almost insupportable sense of acrimony; and snuffed up the nostrils excite violent sneezing. Magendie states that, when taken internally in the dose of a quarter of a grain, they promptly produce abundant alvine evacuations, and in larger doses provoke more or less violent vomiting. Dr. Turnbull, on the contrary, says that he has very seldom found them to purge, even when largely administered, and that not unfrequently a state of constipation comes on during their employment, requiring the use of aperient medicine. According to this author, their first effect, when given in moderate doses, is a feeling of warmth in the stomach, gradually extending itself over the abdomen and lower part of the chest, and ultimately to the head and extremities. If the medicine is continued, this feeling of warmth is followed by a sense of tingling, similar to that produced by the external use of the medicine, which manifests itself in different parts of the body and sometimes over the whole surface, and is frequently accompanied by perspiration and some feeling of oppression. Occasionally also diuresis is produced. A still further continuance of the medicine, or the use of large doses excites nausea and vomiting. It occasions no narcotic effects.

The diseases in which veratria has been employed are chiefly gout, rheumatism, and neuralgia. Dr. Turnbull has found it useful also in dropsy and in diseases of the heart, particularly those of a functional character. He thinks he has also seen it do good in organic diseases of this organ, but chiefly by acting as a diuretic and thereby removing effusion in the pericardium. Veratria has also been employed in various nervous affections, as paralysis, hooping-cough, epilepsy, hysteria, and disorders dependent upon spinal irritation. For internal use the salts of veratria are preferred. From one-twelfth to one-sixth of a grain may be given in the form of pill, and repeated every three hours till the effects of the medicine are experienced. Dr. Turnbull prefers the tartrate, as less disposed to irritate the stomach. The sulphate or acetate, however, may be used. Any one of these salts

may be readily prepared by treating veratria with water acidulated with the acid to perfect neutralization, and then evaporating to dryness.

But veratria is much more employed externally than by the stomach; and is applicable in this way, to all the complaints already mentioned. It may be used either dissolved in alcohol, or rubbed up with lard or other unctuous substance, in the proportion of from ten to twenty grains or more to the ounce. Of the ointment thus prepared, Dr. Turnbull directs a portion of the size of a large nut to be rubbed upon the skin over the part affected, night and morning, from five to fifteen minutes, or until the more urgent symptoms are relieved. The veratria may be used in this way to the amount of from four to eight grains in the day. Care must be taken that the cuticle is sound over the parts to which it is applied. When the skin is irritable, smaller quantities than those above mentioned must be used.

W.

VINA MEDICATA.

Medicated Wines.

The advantages of wine as a pharmaceutic menstruum are, that in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change; while, at the same time, it is less stimulant than rectified or proof spirit, both from its smaller proportion of alcohol, and from the modified state in which this fluid exists in its composition. The acid which it usually contains, serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition; and even the strongest acquire such a liability from the principles which they extract from vegetable substances; so that medicated wines, though they keep much better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant; and the preparations, therefore, made with them, are of unequal strength. From these causes, few medicated wines are at present retained. In the choice of wine, the purest and most generous should be selected. Sherry as directed by the U. S. and British Pharmacopœias, Teneriffe, or Madeira, should be preferred. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, without heat, and should be kept in well stopped bottles in a cool place.

W.

VINUM ALOËS. U. S., Lond., Ed., Dub. *Wine of Aloes.*

“Take of Aloes, in powder, *an ounce*; Cardamom [seeds], bruised, Ginger, bruised, each, *a drachm*; Wine [Sherry] *a pint*. Macerate for fourteen days, with occasional agitation, and filter through paper.” U. S.

“Take of Aloes, in powder, *two ounces*; Canella, in powder, *four drachms*; Sherry Wine *two pints* [Imperial measure]. Macerate for fourteen days, occasionally stirring, and filter.” Lond.

“Take of Socotrine or East Indian Aloes *an ounce and a half*; Cardamom Seeds, ground, Ginger, in coarse powder, of each, *a drachm and a half*; Sherry *two pints*. Digest for seven days, and strain through linen or calico.” Ed.

The Dublin College takes *four ounces* of Socotrine aloes and *an ounce* of canella, powders them separately, mixes them, and macerates for fourteen days in a menstruum consisting of *three pints* of Sherry wine and *a pint* of proof spirit.

The wine of aloes is a warm stomachic purgative, useful in constipation dependent on a want of due irritability of the alimentary canal, and in complaints connected with this state of the bowels. It has long been used in chlorosis, amenorrhœa, dyspepsia, gout, paralysis, &c. It is said to leave behind it a more lax condition of the bowels than most other cathartics. The dose as a stomachic is one or two fluidrachms, as a purgative from half a fluidounce to two fluidounces. W.

VINUM COLCHICI RADICIS. U. S. VINUM COLCHICI. Lond., Ed. *Wine of Colchicum Root.*

"Take of Colchicum Root, well bruised, *a pound*; Wine [Sherry] *two pints*. Macerate for fourteen days, with occasional agitation; then express strongly, and filter through paper.

"Wine of Colchicum Root may also be prepared by macerating as above, then transferring to an apparatus for displacement, and, after the liquor has ceased to pass, pouring so much Wine upon the residue that the filtered liquor obtained may measure *two pints*." U. S.

"Take of dried Meadow-saffron Cormus [bulb], sliced, *eight ounces*; Sherry Wine *two pints* [Imperial measure]. Macerate for fourteen days, and filter." Lond.

The *Edinburgh College* directs the same quantities of materials as the London, and orders digestion for seven days, straining, strong expression, and filtering.

This is intended to be a saturated vinous tincture of colchicum. The dried bulb is necessarily employed in this country, as the fresh is not kept in the shops. As the colchicum imported into the United States is of variable strength, the only method by which an active preparation can be ensured, is to employ a large quantity of the bulb in proportion to that of the menstruum. If the former should happen to be in excess, no other injury could result than a slight pecuniary loss; while a deficiency in the strength of the preparation would frequently be of serious detriment in urgent cases of disease. We have never been disappointed in obtaining the effects of colchicum from the wine which we knew to have been prepared according to the direction of the U. S. Pharmacopœia; while that which has been made with a smaller quantity of the bulb has often failed in our hands. The dose is from ten minims to a fluidrachm, to be repeated three or four times a day, or more frequently in severe cases, till its effects are experienced. In gout it is frequently given in connexion with magnesia and its sulphate; and in neuralgic cases we have found much advantage from combining it with the solution of sulphate of morphia, especially when we have desired to give it a direction rather to the skin than the bowels. It has been employed externally with asserted advantage in rheumatism. In over doses it is capable of producing fatal effects. Death is said to have occurred in one instance from two drachms of the wine; but much more would probably in general be requisite to produce this result. W.

VINUM COLCHICI SEMINIS. U. S. *Wine of Colchicum Seed.*

"Take of Colchicum Seed, bruised, *four ounces*; Wine [Sherry] *two pints*. Macerate for fourteen days, with occasional agitation; then express, and filter through paper." U. S.

As the seeds of colchicum are less liable to injury than the bulb, and are, therefore, of more uniform strength, there is not the same necessity for preparing a saturated tincture. As directed, however, in the old Pharmacopœia, this wine was too feeble; and in the last edition, the proportion

of the seeds has very properly been doubled. It now corresponds in strength with the *tincture* of colchicum seeds. (See *Tinctura Colchici Seminis*.) Dr. Williams, who introduced the seeds into use, recommends that they should not be bruised, as their virtues reside in their outer coat; but this is probably a mistake. The dose of this wine is one or two fluidrachms. Two fluidounces have proved fatal. W.

VINUM ERGOTÆ. U. S. *Wine of Ergot.*

"Take of Ergot, bruised, *two ounces*; Wine [Sherry] *a pint*. Macerate for fourteen days, with occasional agitation; then express, and filter through paper." U. S.

The dose of this wine is for a woman in labour two or three fluidrachms; for other purposes, one or two fluidrachms, to be repeated several times a day, and gradually increased if necessary. W.

VINUM GENTIANÆ. Ed. *Wine of Gentian.*

"Take of Gentian, in coarse powder, *half an ounce*; Yellow Bark, in coarse powder, *one ounce*; Bitter-orange Peel, dried and sliced, *two drachms*; Canella, in coarse powder, *one drachm*; Proof Spirit *four fluidounces and a half*; Sherry *one pint and sixteen fluidounces* [Imperial measure]. Digest the root and barks for twenty-four hours in the Spirit; add the Wine, and digest for seven days more; strain and express the residuum strongly, and filter the liquors." Ed.

This is a stomachic bitter, sometimes employed to promote appetite and invigorate digestion. The dose is from four to eight fluidrachms. W.

VINUM IPECACUANHÆ. U. S., Lond., Ed., Dub. *Wine of Ipecacuanha.*

"Take of Ipecacuanha, bruised, *two ounces*; Wine [Sherry] *two pints*. Macerate for fourteen days, with occasional agitation; then express, and filter through paper." U. S.

The London College takes *two ounces and a half* of the bruised root, and *two pints* [Imperial measure] of Sherry wine; the Dublin, *two ounces* of the bruised root, and *two pints* of Sherry wine; both macerate for two weeks. The Edinburgh College employs the same proportions as the London, and digests for a week.

The preparations of the different Pharmacopœias are virtually of the same strength. Wine of ipecacuanha possesses all the medical properties of the root, and may be used as a substitute when it is desirable to administer the medicine in a liquid form. As it is milder, without being less efficacious than antimonial wine, it is in some instances preferable as an emetic in infantile cases, especially when the antimonial, as not unfrequently happens, is disposed to produce griping and irritation of the bowels. Under the same circumstances, it may be used as an expectorant and diaphoretic; and the effects of the Dover's powder may be obtained by combining it with laudanum or other liquid preparation of opium. The dose as an emetic for an adult is a fluidounce; as an expectorant and diaphoretic, from ten to thirty minims. A fluidrachm may be given as an emetic to a child one or two years old, and repeated every fifteen minutes till it operates. W.

VINUM OPII. U. S., Lond., Ed., Dub. *Wine of Opium. Sydenham's Laudanum.*

"Take of Opium, in powder, *two ounces*; Cinnamon bruised, Cloves bruised, each, *a drachm*; Wine [Sherry] *a pint*. Macerate for fourteen days, with occasional agitation; then express, and filter through paper." U. S.

The *London College* takes *two ounces and a half* of purified extract of opium, *two drachms and a half* of bruised cinnamon, *the same quantity* of bruised cloves, and *two pints* [Imperial measure] of Sherry wine; and macerates for fourteen days. The *Edinburgh College*, to the same quantity of cinnamon and cloves, adds *three ounces* of opium, and *two pints* [Imperial measure] of Sherry wine, and digests for a week. The *Dublin College* takes *an ounce* of Turkey opium, *a drachm* of cinnamon, *a drachm* of cloves, and *a pint* of Sherry wine, and macerates for eight days.

The wine made according to the directions of the U. S. Pharmacopœia is a stronger preparation than that of the British Colleges, being a saturated vinous tincture of opium. It contains about the same proportions of the ingredients as the *laudanum of Sydenham*, from which it differs only in wanting a drachm of saffron. The spices which it contains are thought to adapt it to certain states of the stomach or system, in which the simple tincture of opium is found to produce unpleasant effects; but the same end may be obtained by an extemporaneous addition of some aromatic oil to the latter. Mr. Ware recommends it as a local application to the eye, in the latter stages of ophthalmia, when the vessels of the conjunctiva still remain turgid with blood. Two or three drops are introduced into the eye every morning till the redness disappears. The dose of the wine of opium is the same with that of the tincture. W.

VINUM RHEI. U. S., Ed. *Wine of Rhubarb.*

“Take of Rhubarb, bruised, *two ounces*; Canella, bruised, *a drachm*; Diluted Alcohol *two fluidounces*; Wine [Sherry] *a pint*. Macerate for fourteen days, with occasional agitation; then express, and filter through paper.” U. S.

The *Edinburgh College* takes *five ounces* of rhubarb, in coarse powder, *two drachms* of canella, in coarse powder, *five fluidounces* of proof spirit, and *one pint fifteen fluidounces* [Imperial measure] of Sherry wine, and digests for seven days.

This is a warm cordial laxative, applicable to debilitated conditions of the system or alimentary canal requiring evacuation of the bowels. The dose is from one to four fluidrachms or more, according to the amount of effect required, and the condition of the patient. W.

VINUM TABACI. U. S., Ed. *Wine of Tobacco.*

“Take of Tobacco, cut in pieces, *an ounce*; Wine [Sherry] *a pint*. Macerate for fourteen days, with occasional agitation; then express, and filter through paper.” U. S.

The *Edinburgh College* takes *three ounces and a half* of tobacco and *two pints* [Imperial measure] of Sherry wine, and digests for seven days.

The dose of the wine of tobacco, as a diuretic, is from ten to thirty minims. It is very seldom used. W.

VINUM VERATRI ALBI. U. S. VINUM VERATRI. Lond. *Wine of White Hellebore.*

“Take of White Hellebore [root], bruised, *four ounces*; Wine [Sherry] *a pint*. Macerate for fourteen days, with occasional agitation; then express, and filter through paper.” U. S.

The *London College* takes *eight ounces* of the sliced root, and *two pints* [Imperial measure] of Sherry wine, and macerates for fourteen days.

It has been supposed that the wine of white hellebore, in consequence of the veratria which it contains, would act in the same manner with colchicum in the cure of gout and rheumatism; but it is uncertain and occasionally

violent in its operation, and is very little used. The dose is ten minims two or three times a day, to be gradually increased till the peculiar effects of the medicine are experienced. W.

ZINCUM.

Preparations of Zinc.

ZINCI ACETAS. U.S. *Acetate of Zinc.*

“Take of Acetate of Lead a pound; Zinc, granulated, nine ounces; Distilled Water three pints. Dissolve the Acetate of Lead in the Water and filter. Add the Zinc to the solution, and agitate them occasionally together, in a stopped bottle, for five or six hours, or until the liquid yields no precipitate with a solution of iodide of potassium. Filter the liquor, evaporate it with a moderate heat to one-fifth, and set it aside to crystallize. Pour off the liquid, and dry the crystals on bibulous paper. Should the crystals be coloured, dissolve them in Distilled Water, and, having heated the solution, drop into it, while hot, a filtered solution of Chlorinated Lime until it ceases to let fall sesquioxide of iron; then filter the liquor, acidulate it with a few drops of Acetic Acid, evaporate, and crystallize.” U. S.

In this process the lead of the acetate of lead is wholly precipitated by the zinc, which forms with the acetic acid the acetate of zinc in solution. In order to be sure that the solution is entirely free from lead, it is tested with iodide of potassium which will produce a yellow precipitate in case any of the metal remain unprecipitated. The crystals of acetate of zinc, at first obtained, are apt to be coloured from the presence of iron. In this case they are directed to be dissolved in distilled water and treated with a solution of chlorinated lime. The chlorine of this compound, by decomposing water, furnishes oxygen which sesquioxidizes the iron and thus renders it insoluble. During the heating, a small portion of acetic acid is generally lost, and hence the necessity of acidulating with a few drops of this acid before crystallizing. After the evaporation of the first solution to one-fifth, it should be acidulated if found deficient in acid. This process is better than the one by double decomposition between sulphate of zinc and acetate of lead, formerly adopted in our Pharmacopœia; as the product is purer, the materials cheaper, and the manipulation easier. (See the paper of Mr. Ambrose Smith on this acetate, contained in the seventh volume of the *Amer. Journ. of Pharmacy*.)

Properties, &c. Acetate of zinc, when carefully crystallized, is in colourless, transparent hexagonal plates which effloresce in a dry air. As found in the shops it is in opaque, white, micaceous scales. It is very soluble in water, moderately soluble in rectified spirit, and has an astringent, metallic, very disagreeable taste. The solution yields a white precipitate with ferrocyanuret of potassium and hydrosulphate of ammonia. The precipitate thrown down by ammonia, is entirely redissolved by an excess of the precipitant; but if iron be present, though thrown down, it will not be redissolved. Acetate of zinc is decomposed by the mineral acids, with the escape of acetous vapours. By destructive distillation, it yields a considerable quantity of acetone. (See page 782.) It consists of one eq. of acetic acid 51.48, one of protoxide of zinc 40.3, and seven of water 63=154.78.

Medical Properties and Uses. Acetate of zinc is used as an external remedy only, for the most part as an astringent collyrium in ophthalmia, and injection in gonorrhœa, after the acute stage in these affections has

passed. It is official, in the crystallized state, only in the U. S. Pharmacopœia. The Dublin College orders a tincture of it; but this is not an eligible preparation. It is certainly proper to have the salt official in the solid form; as when in that state it may be prescribed in any desired proportion in solution, according to the nature of the case to which it is to be applied. The strength of the solution, usually employed, is one or two grains to a fluidounce of distilled water. B.

ZINCI ACETATIS TINCTURA. *Dub. Tincture of Acetate of Zinc.*

“Take of Sulphate of Zinc, Acetate of Potassa, each, *one part*. Rub them together, and add of Rectified Spirit *sixteen parts*. Macerate for a week, with occasional agitation, and filter through paper.” *Dub.*

In this process, the acetate of potassa first dissolves in the rectified spirit, and then reacts upon the sulphate of zinc, and in consequence of a double decomposition, sulphate of potassa and acetate of zinc are formed. Of these salts, the latter only is soluble in the spirit, while the former remains undissolved, and is removed by filtration. As the acetate of potassa is used in excess, this preparation may be viewed as a spirituous solution of both the acetate of potassa and acetate of zinc. The rectified spirit ordered is hardly sufficient to dissolve all the acetate of zinc formed.

Properties, &c. This tincture is transparent and colourless, and when evaporated nearly to dryness, affords crystals of acetate of zinc, recognizable by their shape and micaceous appearance. (See *Zinci Acetas*.) It is employed as an astringent collyrium and injection, but requires to be diluted with water. B.

ZINCI CARBONAS PRÆPARATUS. *U. S. CALAMINA PRÆPARATA. Lond., Ed. ZINCI CARBONAS IMPURUM PRÆPARATUM. Dub. Prepared Carbonate of Zinc. Prepared Calamine.*

“Take of Carbonate of Zinc *a convenient quantity*. Heat it to redness, and afterwards pulverize it; then reduce it to a very fine powder in the manner directed for Prepared Chalk.” *U. S.*

The *London* and *Dublin Colleges* prepare calamine by processes agreeing with the above. The *Edinburgh College* places the prepared substance in the list of the *Materia Medica* with this explanatory note—“levigated impure carbonate of zinc.”

The nature, properties, and composition of the native carbonate of zinc have been explained under another head. (See *Zinci Carbonas*.) The object of this process is to bring it to the state of an impalpable powder. It is first calcined, to render it more readily pulverizable, and then levigated and elutriated. During the calcination, water and more or less carbonic acid are driven off; so that little else remains but the oxide of zinc, and the earthy impurities originally existing in the mineral. For the nature of these impurities, see page 748. Considering the objection to this preparation on account of impurity, which is very variable in amount, it would, perhaps, be an improvement to discard the native carbonate altogether, and to use in its stead a pure artificial carbonate, obtained by double decomposition between sulphate of zinc and carbonate of ammonia.

Properties, &c. Prepared carbonate of zinc is in the form of a pinkish or flesh-coloured powder, of an earthy appearance. Sometimes it is made up into small masses. When pure it dissolves in the mineral acids with effervescence. It is used only as an external application, being employed as a mild astringent and exsiccant in excoriations and superficial ulcerations.

For this purpose, it is dusted on the part, and hence the necessity for its being very finely levigated. It is often employed in the form of cerate. By an oversight, the London College has directed the calamine, and not the *prepared* calamine to make the cerate. (See *Ceratum Zinci Carbonatis*.)

Off. Prep. Ceratum Zinci Carbonatis, *U. S.*, *Ed.*, *Dub.*

B.

ZINCI CHLORIDUM. *U. S.* Chloride of Zinc. Butter of Zinc.

“Take of Zinc, in small pieces, *two ounces and a half*; Nitric Acid, Prepared Chalk, each, *a drachm*; Muriatic Acid *a sufficient quantity*. To the Zinc, in a glass or porcelain vessel, add gradually sufficient Muriatic Acid to dissolve it; then strain, add the Nitric Acid, and evaporate to dryness. Dissolve the dry mass in Water, add the Chalk, and, having allowed the mixture to stand for twenty-four hours, filter, and again evaporate to dryness.” *U. S.*

This process is that of the French Codex slightly modified. A chloride of zinc is first formed in solution by dissolving zinc in muriatic acid. The nitric acid added has the effect to sesquioxidize and render insoluble any iron which may have formed an impurity in the zinc employed. By evaporating to dryness and redissolving in water, the sesquioxide of iron is left. Lastly, in order to remove any excess of acid, a small portion of chalk is added; and the mixture, after standing, is filtered to remove the excess of chalk, and then evaporated to dryness.

M. Righini prepares this chloride by double decomposition between solutions of chloride of barium and sulphate of zinc. Sulphate of baryta is precipitated, and chloride of zinc remains in solution, from which it is obtained in white flaky crystals by due evaporation. (*Am. Journ. of Pharm.* xiv. 350, from the *Journ. de Chim. Méd.*)

Properties, &c. Chloride of zinc is a whitish, semitransparent, deliquescent substance, having the softness of wax. It is wholly soluble in water, alcohol, and ether. When exposed to heat it first melts and then sublimes. When pure it gives white precipitates with ferrocyanuret of potassium and hydrosulphate of ammonia. A blue precipitate with the former test would indicate iron, a black one with the latter, lead. It consists of one eq. of zinc 32·3, and one of chlorine 35·42 = 67·72.

Medical Properties and Uses. This chloride was introduced into medicine by Papenguth, and subsequently recommended by Prof. Hancke, of Breslau, and Dr. Canquoin, of Paris. Internally it has been given, as an alterative and antispasmodic, in scrofula, epilepsy, chorea, and, combined with hydrocyanic acid, in facial neuralgia. Its chief employment, however, has been externally as an escharotic, applied to scirrhus and cancerous affections, and to ulcers of an anomalous and intractable character. When thus used it acts not merely by destroying the diseased structure, but by exciting a new and healthier action in the surrounding parts. As a caustic it has the advantage of not giving rise to constitutional disorder from absorption, an effect which is sometimes produced by the arsenical preparations.

Dr. Canquoin prepares the chloride of zinc as an escharotic, by thoroughly and quickly mixing it with wheat flour and water, into a paste of four different strengths, containing an ounce of the chloride, severally incorporated with two, three, four, and five ounces of flour; fifteen drops of water being added for every ounce of flour, or sufficient to form the paste. It is applied in cakes of from a twelfth to a third of an inch in thickness, and produces an eschar more or less deep (from a line to an inch and a half), according to the thickness of the paste, the length of the application,

and the nature of the part acted on. The strongest paste is applied to lardaceous and fibro-cartilaginous structures; the second to carcinomatous tumours, and very painful cancers which have not much thickness, and the third to cancerous affections in persons who have a dread of violent pain. These preparations, applied to the skin denuded of its cuticle by means of a blister, excite in a few minutes a sensation of heat, and afterwards violent burning pain. The eschar, which is white, very hard, and thick, falls off, by the aid of an emollient poultice, between the eighth and twelfth day. To destroy thick cancerous tumours, having an uneven surface, and situated in fleshy parts, Dr. Canquoin uses a caustic formed of one part of chloride of zinc, half a part of chloride of antimony, and two and a half of flour, made up with water into a paste. In all cases, the caustic is to be reapplied, after the falling off of the eschar, until the whole morbid structure is destroyed. Instead of flour, Dr. Alex. Ure, of Glasgow, mixes the chloride with pure anhydrous sulphate of lime in impalpable powder. He states that it has the advantages of furnishing a porous medium from which the escharotic gradually exudes into the morbid structure, and of forming afterwards, by acquiring a firmer consistence, an impervious case for the eschar. Mr. Calloway, of Guy's Hospital, has employed the chloride of zinc with considerable success in the treatment of *nævi materni*. He rubs it at intervals on the part until the skin becomes slightly discoloured. Mr. Guthrie has used it with success for penetrating the hard case of new bone which forms over a sequestrum, in order to expose the latter, so as to permit of its convenient extraction. M. Gaudriot recommends it in gonorrhœa in both sexes, as having remarkable remedial powers. For men he uses an injection composed of from 24 to 36 drops of the liquid chloride, mixed with four fluidounces of water. A small quantity only is injected about an inch down the urethra two or three times a day. For women he employs a vaginal suppository, formed of five drops of the liquid chloride, half a grain of sulphate of morphia, and three drachms of a paste consisting of three parts of starch, two of mucilage of tragacanth, and one of sugar. The suppository is introduced every day, or every second day. By the liquid chloride is probably meant a neutral solution of zinc in ordinary muriatic acid.

For internal exhibition, the most convenient form is solution in the spirit of sulphuric ether in the proportion of half an ounce of the chloride to three fluidounces of the menstruum. Of this from four to eight drops may be given twice a day. B.

ZINCI OXIDUM. *U.S., Ed.* ZINCI OXYDUM. *Lond., Dub.*
Oxide of Zinc.

“Take of Sulphate of Zinc *a pound*; Carbonate of Ammonia *six ounces and a half*; Distilled Water *three gallons*. Dissolve the Sulphate of Zinc and Carbonate of Ammonia, separately, in twelve pints of the Distilled Water, strain the solutions, and mix them. Wash the precipitate frequently with water, and expose it to a strong heat so as to drive off the carbonic acid.” *U. S.*

The *London* process is essentially the same with the above, which was adopted from the *London Pharmacopœia*.

“Take of Sulphate of Zinc *twelve ounces*; Carbonate of Ammonia *six ounces*. Dissolve each in *two pints* [Imperial measure] of Water; mix the solutions; collect the precipitate on a filter of linen or calico; wash it thoroughly; squeeze and dry it, and expose it for two hours to a red heat.” *Ed.*

“Take of Zinc, broken into pieces, *any quantity*. Throw it at intervals

into a sufficiently deep crucible heated to redness, and placed with its mouth inclined towards the mouth of the furnace. After the injection of each piece of Zinc, cover the crucible with another inverted over it, but loosely, so that the air may not be excluded. Preserve the light and very white sublimed powder for use." *Dub.*

Oxide of zinc is now obtained in the *U. S.*, *London*, and *Edinburgh* Pharmacopœias by precipitating a solution of sulphate of zinc by one of carbonate of ammonia, and then igniting the carbonate of zinc thus formed to drive off the carbonic acid. During the precipitation, half an equivalent of carbonic acid is given off with effervescence from the carbonate of ammonia, which, it will be recollected, is a sesquicarbonate. The old formula directed the precipitation of the sulphate by ammonia, and it was supposed that the precipitate was the oxide of zinc; but it has been proved that it is not a pure oxide, but the oxide mixed with the subsulphate of zinc. The London College first abandoned this process for the one above explained, and its example has been followed by the revisers of the *U. S.* and *Edinburgh* Pharmacopœias. In the process of the *Dublin College* the oxide is obtained by burning the metal. Zinc melts at 773° , and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, generating the oxide in the form of very light and white flocculi, resembling carded wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. It is to prevent loss from the latter circumstance, that the crucible is inclined towards the mouth of the furnace, a position which prevents the axis of the crucible from coinciding with the direction of the draught. The zinc is directed to be thrown into the crucible in successive pieces; but a better and more expeditious method is to put the whole of the zinc, intended to be converted into oxide, into a crucible large enough to be only two-thirds filled by it. Heat being applied, the zinc soon melts, and afterwards catches fire, and the oxide, as it is formed, is to be removed by means of a ladle with a long handle, until the whole of the metal is consumed.

Properties, &c. Oxide of zinc is an inodorous, tasteless, white powder, insoluble in water and alcohol. It dissolves readily in acids and in potassa, soda, and ammonia, but not in their carbonates. When heated moderately it becomes yellow; but upon cooling it regains its white colour, unless iron is present, when the yellow tint remains. At a low white heat it fuses, and at a full white one sublimes. When prepared by combustion, it was formerly called *pompholix*, *nihil album*, *lana philosophica*, and *flowers of zinc*. This oxide is often impure. Much of that sold in the shops is the carbonate and effervesces with acids. Its neutral solution in acids should give a white precipitate with ferrocyanuret of potassium and hydrosulphate of ammonia. If the precipitate with the former test is bluish-white, iron is indicated; if black with the latter, lead is shown. When obtained by means of caustic ammonia, it will contain the subsulphate, the acid of which may be detected by dissolving the oxide in nitric acid, and precipitating by nitrate of baryta. The precipitate produced in the pure salt by ammonia should be entirely soluble in an excess of the precipitant. If iron be present it will be thrown down and left undissolved as a yellowish powder. If the oxide contain white lead or chalk, it will not be entirely soluble in dilute sulphuric acid, but an insoluble sulphate of lead or of lime will be left behind. Oxide of zinc consists of one eq. of zinc 32.3, and one of oxygen 8=40.3.

Medical Properties and Uses. Oxide of zinc is tonic and antispasmodic. It has been given in chorea, epilepsy, hooping-cough, spasm of the stomach dependent on dyspepsia, and other similar affections. Externally it is employed as an exsiccant to excoriated surfaces; sometimes by sprinkling it on the affected part, but generally in the form of ointment. (See *Unguentum Zinci Oxidi*.) The dose is from two to eight grains or more, several times a day, given in the form of pill.

Off. Prep. Unguentum Zinci Oxidi, U. S., Lond., Ed., Dub. B.

ZINCI SULPHAS. U. S., Lond., Ed., Dub. *Sulphate of Zinc, White Vitriol.*

“Take of Zinc, in small pieces, *four ounces*; Sulphuric Acid *six ounces*; Distilled Water *four pints*. To the Zinc and Water, previously introduced into a glass vessel, add by degrees the Sulphuric Acid, and, when the effervescence shall have ceased, filter the solution through paper; then boil it down till a pellicle begins to form, and set it aside to crystallize.” U. S.

“Take of Zinc, in small pieces, *five ounces*; Diluted Sulphuric Acid *two pints* [Imperial measure]. Pour gradually the Diluted Sulphuric Acid upon the pieces of Zinc, and, the effervescence being finished, strain the liquor; then boil it down until a pellicle begins to appear. Lastly, set it aside that crystals may form.” Lond.

“This salt may be prepared either by dissolving fragments of Zinc in Diluted Sulphuric Acid till a neutral liquid be obtained, filtering the solution, and concentrating sufficiently for it to crystallize on cooling,—or by repeatedly dissolving and crystallizing the impure Sulphate of Zinc of commerce, until the product when dissolved in water does not yield a black precipitate with tincture of galls, and corresponds with the characters laid down for Sulphate of Zinc in the list of the *Materia Medica*.” Ed.

“Take of Zinc, broken into small pieces, *thirteen parts*; Sulphuric Acid *twenty parts*; Water *one hundred and twenty parts*. Put the Zinc into a glass vessel, and gradually add the Acid, previously diluted with the Water. When the effervescence has ceased, digest for a little while. Then filter and evaporate the solution, and after sufficient concentration, set it aside that crystals may form.” Dub.

By this process, a pure and crystallized sulphate of zinc is obtained. Strong sulphuric acid has very little action on zinc, but when *diluted*, water is instantly decomposed, and while its hydrogen escapes with rapid effervescence, its oxygen combines with the zinc, and the oxide formed, uniting with the sulphuric acid, generates the sulphate of the oxide of zinc. Thus it is perceived that *hydrogen* is a collateral product of the process, which, being easily performed, is generally resorted to for obtaining this gas. The proportion of the zinc to the strong acid is as 4 to 6 in the U. S. process; as 4 to 5.33* nearly in the London; and as 4 to 6.15 in the Dublin. The equivalent numbers give the ratio of 4 to 6.08; which indicates that the U. S. numbers approach very nearly to the true proportion. If the materials be mixed at once, without any precaution, the effervescence of hydrogen is apt to be excessive, and to cause the overflowing of the liquid. This is avoided by the London and Dublin direction to add the diluted acid gradually to the zinc, and more completely still in the U. S. formula, in which the solution of the zinc is commenced by a very dilute acid, which, as the action slackens, is made by degrees stronger

* This number is calculated on the assumption that a fluidounce [Imperial measure] of the London diluted acid contains eighty grains of strong acid.

and stronger, by the addition, at intervals, of small portions of fresh acid. The formula of the Edinburgh Pharmacopœia is a new one, adopted on the last revision of that work. It embraces directions for obtaining the salt either by direct combination, or by purifying the white vitriol of commerce from iron by repeated solutions and crystallizations.

Preparation on the Large Scale. Sulphate of zinc in an impure state, as it occurs in commerce, is called *white vitriol*. It is manufactured by roasting *blende* (native sulphuret of zinc) in a reverberatory furnace. This mineral, besides sulphuret of zinc, contains small quantities of the sulphurets of iron, copper, and lead; and by roasting is converted, in consequence of the oxidation of its constituents, into sulphate of zinc, mixed with the sulphates of iron, copper, and lead. The roasted matter is then lixiviated, and the solution obtained, after having been allowed to settle, is concentrated by evaporation; so that, on cooling, it may concrete into a white crystalline mass, resembling lump sugar. In this state, it always contains sulphate of iron, and sometimes a small portion of sulphate of copper. It may be purified to a certain extent by dissolving it in water, and boiling the solution with oxide of zinc, which converts the sulphates of iron and copper, by precipitating their bases, into sulphate of zinc. The purified solution is then decanted or filtered, and, after due evaporation, is allowed to crystallize. It has generally been proposed to purify the white vitriol of commerce by digesting its solution with metallic zinc, under an impression that this is capable of precipitating all the foreign metals; but, according to Berzelius, though it will precipitate copper readily, it has no action on the sulphate of iron. The best way of separating iron is to add to the solution of the sulphate of zinc a filtered solution of chlorinated lime, which will sesquioxidize the iron and render it insoluble. (Dr. W. R. Fisher in the *Am. Journ. of Pharm.* viii. 107.)

Properties, &c. Sulphate of zinc is a colourless transparent salt, having a disagreeable, metallic, styptic taste, and crystallizing usually in small four-sided prisms, terminated by four-sided pyramids. Its crystals have considerable resemblance to those of sulphate of magnesia. It effloresces slightly in dry air, and, though neutral in composition, is still capable of reddening vegetable blues. It dissolves in two and a half times its weight of cold water, and in less than its weight of boiling water, and is insoluble in alcohol. When heated, it dissolves in its water of crystallization, which gradually evaporates; and by a prolonged ignition, the whole of the acid is expelled, and the oxide of zinc left. The caustic alkalies throw down a white precipitate of mixed oxide and subsulphate, which is redissolved by the alkali when added in excess. If iron be present it is precipitated also, but not redissolved. The alkaline carbonates precipitate the metal in the state of white carbonate. Pure sulphate of zinc is precipitated white by ferrocyanuret of potassium. If copper be present, ammonia will produce a blue tinge; if iron, the ferrocyanuret of potassium will cause a bluish-white precipitate instead of a white one. Sulphate of zinc is incompatible with alkalies and alkaline carbonates, hydrosulphates, lime-water, and astringent vegetable infusions.

The impure commercial variety of sulphate of zinc, called white vitriol, is in the form of irregular opaque masses, having some resemblance to lump sugar. The lumps usually present, here and there, on the surface, yellow stains, produced by the sesquioxide of iron. It is less soluble than the pure salt, on account of its containing less water of crystallization.

Composition. Crystallized sulphate of zinc consists of one eq. of

sulphuric acid 40·1, one of oxide of zinc 40·3, and seven of water 63=143·4. The white vitriol of commerce contains but three eqs. of water.

Medical Properties and Uses. This salt is tonic, astringent, and, in large doses, a prompt emetic. As a tonic, it is supposed to be well suited to cases of debility attended with irritation, being less heating than sulphate of iron. In dyspepsia it has been used with advantage in very minute doses, as for instance, a quarter of a grain, repeated several times a day; but if its good effects are not soon apparent, it should be laid aside. In obstinate intermittents, it is a valuable resource, and may be given alone, or conjoined with cinchona or sulphate of quinia. But it is in spasmodic diseases, such as epilepsy, chorea, pertussis, &c., that it has been principally employed as an internal remedy. Dr. Paris speaks of its efficacy in high terms, in spasmodic cough, especially when combined with camphor or myrrh, and "in affections of the chest attended with inordinate secretion." As an astringent it is chiefly employed externally. In this mode of application, its solution constitutes a good styptic to bleeding surfaces, and is frequently resorted to as an injection in fluor albus and the advanced stages of gonorrhœa, and as a collyrium in ophthalmia. In some conditions of ulcerated sorethroat, it is found useful as a gargle. It has been used also in solution with success as a remedy in nasal polypi, in the proportion of two scruples gradually increased to an ounce of the salt to seven fluidounces of water, applied by means of lint and by injection. (*Am. Journ. of Med. Sci.* xix. 251.) Before the discovery of tartar emetic, sulphate of zinc was almost exclusively employed to produce vomiting; but at present its use as an emetic is restricted principally to the dislodging of poisons, for which purpose its property of operating rapidly renders it particularly well suited. The dose, as a tonic, is from one to two grains; as an emetic, from ten to thirty grains. To children affected with whooping cough, it may be given in doses of from an eighth to a quarter of a grain two or three times a day. When used as a collyrium, injection, gargle, or wash for indolent ulcers, from one to three grains, or more, may be dissolved in a fluidounce of water. For medical purposes, the crystallized salt should be used, and in no case the impure white vitriol of commerce.

APPENDIX.

I. DRUGS AND MEDICINES NOT OFFICIAL.*

IN the progress of the medical art, numerous remedies have at different times risen into notice and employment, which, by the revolutions of opinion to which our science is incident, or by the discovery of more efficient substitutes, have so far fallen into disrepute as to have been discarded from general practice, and no longer to hold a place in the official catalogues. Of these, however, some are still occasionally employed by practitioners and referred to by writers, and many retain a popularity as domestic remedies, or among empirics, which they have lost with the medical profession generally. The attention of physicians must, therefore, frequently be called to them in the course of practice; and it is highly desirable to possess some knowledge of their properties and effects, in order to be enabled to judge of their agency in any particular case, and at the same time to avoid the suspicion of incompetence which might attach to the exhibition of entire ignorance in relation to them. The remark is true also of other substances, which, though at no time ranked among regular medicines, are yet habitually employed in families, and the influence of which, either remediate or otherwise, must often enter into our estimate of the causes which produce or modify disease. New medicines, moreover, are frequently brought forward, which, without having obtained the sanction of the medical authorities, are occasionally prescribed, and therefore merit notice. To supply, to a certain extent, the requisite means of information in regard to these extra-official remedies, is the object of the following brief notices, among which are also included accounts of substances not employed as medicines, but usually kept in the drug stores for various purposes connected with the arts, or with domestic convenience. In a work intended for the use as well of the apothecary and druggist, as of the physician and medical student, the introduction of such accounts is obviously proper, if kept in due subordination to the more important object of teaching the properties of medicines, and the mode of preparing them. The authors regret that the limits which practical convenience appears to require in a Dispensatory, do not admit of a more complete enumeration of the various drugs and medicines of the kind above alluded to, or of ampler details in relation to those actually treated of, than will be found in the following pages. They have endeavoured, however, in the selection of objects, to choose those which are likely most frequently to engage the attention of the Medical and Pharmaceutical professions, and, in the extent of the descriptions, to consult as far as possible the relative importance of facts, of which they could not detail the whole. In relation to the nomenclature employed, it may be proper to observe, that all those vegetable remedies, which, not being generally kept in the shops, have no current commercial name, are described under the scientific title of the plant producing them; while other substances are designated by the names which ordinary usage has assigned them.

* By the term official medicines, here as well as elsewhere in this work, are meant such as are embraced in the United States and British Pharmacopœias.

ACETIC ETHER. *Æther Aceticus.* This ether was discovered by Lauraguais, in 1759. It may be formed by several processes, the chief of which are the following:—
 1. Mix 100 parts of alcohol (sp. gr. 0·83) with 63 parts of concentrated acetic acid, and 17 parts of strong sulphuric acid, and distil 125 parts into a receiver, kept cold with wet cloths. 2. Distil to dryness, a mixture of 3 parts of acetate of potassa, 3 of alcohol, and 2 of sulphuric acid, and mix the distilled product with one-fifth of sulphuric acid, and distil a second time an amount of ether equal to the alcohol employed. 3. Distil 2 parts of effloresced acetate of lead, with 1 part of alcohol, and a little more than 1 part of sulphuric acid. In the two latter processes, the acetic acid is set free by the action of the sulphuric acid on the acetate employed.

Acetic ether is colourless, and possesses a very grateful odour, and a peculiar, agreeable taste. Its sp. gr. is 0·866 and its boiling point 160°. It undergoes no change by being kept. By contact of flame, it burns readily, diffusing an acid odour. It dissolves in seven and a half parts of water, and unites in all proportions with alcohol. It consists of one eq. of acetic acid 51·48, one of etherine 28·48, and one of water 9=88·96. It is classed by Thenard as an organic-oxacid ether.

Acetic ether is occasionally used in medicine as a stimulant and antispasmodic. The dose is from fifteen to thirty drops, sufficiently diluted with water. It is sometimes employed externally, in frictions, as a resolvent, and for rheumatic pains.

ACHILLEA MILLEFOLIUM. *Milfoil.* *Yarrow.* This is a perennial herb, common to the old and new continents, though supposed to have been introduced into this country from Europe. It is abundant in old fields, along fences, and on the borders of woods and of cultivated grounds, throughout the United States. It is from a foot to eighteen inches high, and is distinguished by its doubly pinnate minutely divided leaves, from which it derived the name of milfoil, and by its dense corymb of whitish flowers, which appear throughout the summer, from June to September. The whole herb is medicinal. Both the flowers and leaves have an agreeable, though feeble aromatic odour, which continues after drying, and a bitterish, astringent, pungent taste. The aromatic properties are strongest in the flowers, the astringency in the leaves. The plant owes its virtues to a volatile oil, a bitter extractive, and tannin. The oil, which may be obtained separate by distillation with water, has the peculiar flavour of milfoil in a high degree. The active principles are extracted both by water and alcohol. The medical properties of the herb are those of a mild aromatic tonic and astringent. In former times it was much used as a vulnerary, and was also given internally for the suppression of hemorrhages, and of profuse mucous discharges. It has been recommended in intermittents, and as an antispasmodic in flatulent colic, and various affections dependent on nervous debility. At present it is little used. In some parts of Sweden it is said to be employed as a substitute for hops in the preparation of beer, which it is thought to render more intoxicating. It is most conveniently administered in the form of infusion. The volatile oil has been given in the dose of twenty or thirty drops.

ACTÆA SPICATA. *Baneberry.* *Herb Christopher.* This is a perennial, herbaceous, European plant, growing in the woods of mountainous regions, and attaining a height of two feet or more. The root is of a dark brown colour, and bears some resemblance to that of the *Helleborus niger*, for which it is said to be occasionally substituted in some parts of continental Europe. Its odour, in the recent state, is sweetish and rather nauseous, but is in great measure dissipated by drying. The taste is bitterish and somewhat acrid. In its operation on the system, the root is purgative and sometimes emetic, and is capable, in over doses, of producing dangerous effects. It is unknown in this country. We have, however, a native species of *Actæa*—the *A. Americana* of Pursh—of which there are two varieties—the *alba* and *rubra*—distinguished by the colour of their berries, which in the former are white, and in the latter red. They are sometimes called *white* and *red cohosh*, a name derived from the language of the Aborigines. By some botanists they are considered as distinct species, under the name of *Actæa alba*, and *Actæa rubra*. They grow in the rich deep mould of shadowy and rocky woods, from Canada to Virginia. They are said to have been much esteemed by the Indians. Their medical properties are probably similar to those of the *A. spicata*. The name *baneberry*, applied to different species of *Actæa*, was derived from the reputed poisonous properties of their berries.

ADIANTUM PEDATUM. *Maidenhair.* An indigenous fern, the leaves of which are bitterish and aromatic, and have been supposed to be useful in chronic catarrhs and other pectoral affections. A European species known by the same vulgar name, is the *A. Capillus Veneris*, which has similar properties with the former, though feebler, and has been much used as a pectoral on the continent of Europe, from very

early times. It is given in the form of infusion, sweetened with sugar or honey; and a syrup prepared from it is popular in France, under the name of *sirop de capillaire*. The name of maidenhair has also been given to the *Asplenium Trichomanes*, the leaves of which have a mucilaginous, sweetish, somewhat astringent taste, and have been used for the same purposes with those of the plants above mentioned. Another species of *Asplenium*, the *A. Adiantum-nigrum*, has been substituted for the genuine maidenhair, but neither of them has the aromatic flavour of that fern.

ÆSCULUS HIPPOCASTANUM. *Horsechesnut.* The horsechesnut is a native of Asia, and was introduced about the middle of the sixteenth century into Europe, where, as well as in this country, it is now extensively cultivated as an ornamental tree. The fruit and bark have been used in medicine. The fruit abounds in starch, but has a rough, disagreeable, bitter taste, which renders it unfit for food, though it is said to be eaten with avidity by horses, oxen, hogs, and sheep. It may be deprived, in great measure, of the bitter principle by maceration in an alkaline solution. It is asserted that the starch may be readily obtained in a state of purity, and that it excels as an article of diet that procured from the potato. (*Dict. de Mat. Med.*) The powdered kernel of the fruit, snuffed up the nostrils, produces sneezing, and has been used with advantage as a sternutatory in complaints of the head and eyes. The bark of the horsechesnut has attracted much attention on the continent of Europe, as a substitute for cinchona. That of the branches from three to five years old is considered best. It should be collected in the spring. The bark has little odour, but an astringent and bitter, though not very disagreeable taste. It contains, among other ingredients, bitter extractive and tannin, and imparts its virtues to boiling water. By numerous physicians it has been found very efficacious in the treatment of intermittent fever; but has entirely failed in the hands of many others; and certainly cannot be considered comparable to the Peruvian bark in its power over this complaint. It is at present very seldom used, and never in this country. It has been given in substance, decoction, and extract. From half an ounce to an ounce of the powder may be given in the course of twenty-four hours. The decoction is prepared and administered in the same manner as that of Peruvian bark.

AGARIC. *Touchwood. Spunk. Tinder.* This is the product of different species of a genus of mushrooms denominated *Boletus*. Several species of this genus are used as food, several are poisonous, and two at least have been ranked among officinal medicines in Europe. The *Boletus laricis*, which grows upon the larch of the old world, is the *white agaric* or *purging agaric*, of medical writers. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but as found in commerce, is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. It has a sweetish very bitter taste, and consists, according to Braconnot, of 72 parts of resinous matter, 2 of bitter extractive, and 26 of *fungin*, a nutritious animalized principle, constituting the base of the fleshy substance of mushrooms. It contains also benzoic acid and various saline compounds. In the dose of four or six grains it is said to act powerfully as a cathartic; but Lieutaud asserts that it may be given in the quantity of thirty grains or a drachm without sensibly purging. M. Andral has found it useful in checking the night sweats of phthisis. He uses it in doses of eight grains, and gradually increases to a drachm during the day, without any observable inconvenience to the digestive functions. (*Journ. de Pharm.* xx. 599.) In this country it is scarcely employed, though we have met with it in the shops. That which is most esteemed is said to be brought from Siberia, but it is probably produced wherever the European larch tree grows.

The *Boletus ignarius*, or *agaric of the oak*, like the species just described, is compared in shape to the horse's hoof. Its diameter is from six to ten inches. It is soft like velvet when young, but afterwards becomes hard and ligneous. It usually rests immediately upon the bark of the tree, without any supporting footstalk. On the upper surface it is smooth, but marked with circular ridges of different colours more or less brown or blackish; on the under, it is whitish or yellowish and full of small pores; internally it is fibrous, tough, and of a tawny brown colour. It is composed of short tubular fibres compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting it is August or September. It has neither taste nor smell. Its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, azotized matter also in

small quantity, chloride of potassium, and sulphate of lime; and in its ashes are found iron and phosphate of lime and magnesia. It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting hemorrhage, being applied immediately, with pressure, to the bleeding vessel. It was at one time thought to check the hemorrhage by a peculiar property; but it is now believed to act mechanically, like any other soft porous substance, by absorbing the blood and causing it to coagulate, and is not relied on in severe cases. In the obstinate hemorrhage which occasionally takes place from leech bites, especially those of the European leech, it may be used advantageously, though perhaps not more so than well prepared lint. It has been sometimes applied to the purposes of moxa.

When prepared agaric is steeped in a solution of nitre, and afterwards dried, it becomes very readily inflammable, and is applicable to the purposes of tinder. Some recommend the substitution of chlorate of potassa for nitre. The preparation is usually known by the name of *spunk*, and is brought to us from Europe. Spunk or tinder, the *amadou* of the French, is in flat pieces, of a consistence somewhat like that of very soft rotten buckskin leather, of a brownish-yellow colour, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared from various other species of *Boletus*, as the *B. unguilatus*, *B. fomentarius*, *B. ribis*, &c.

AGAVE AMERICANA. *American Agave. American Aloe.* An evergreen succulent plant, indigenous in Florida, Mexico, and other parts of tropical America. This and other species of *Agave* bear a considerable resemblance, in appearance, to the plants of the genus *Aloe*, with which they are sometimes confounded. From the root and leaves of the American agave, when cut, a saccharine juice flows out, which may be converted by evaporation into syrup and even sugar, and by fermentation into a vinous liquor. This juice, when fresh, is said to be laxative, diuretic, and emmenagogue. The expressed juice, evaporated to the consistence of a soft extract, has the property of forming a lather with water, and is employed in some places as a substitute for soap. The fibres of the old leaves, separated by bruising and maceration in water, are used for forming thread.

AGRIMONIA EUPATORIA. *Common Agrimony.* This species of agrimony is a perennial herb, inhabiting Asia, Europe, and North America, and in this country, found in fields and on the borders of woods, and flowering during the summer months. Its stem, which rises from one to three feet in height, is hairy, furnished with interruptedly pinnate leaves, and terminated by a long simple spike of yellow flowers. Both the herb and root have been employed. The former has a weak but agreeable aromatic odour, and a rough, bitterish, somewhat aromatic taste. The fragrance is strongest in the flowers. The root has similar properties; but its taste is more bitter and astringent. A volatile oil may be obtained from the plant by distillation with water. Agrimony is a mild corroborant and astringent. The herb has been considerably employed in relaxed conditions of disease, as in passive hemorrhages, and chronic affections of the mucous membranes. It has been highly recommended also, as a deobstruent in jaundice and visceral obstructions, and as an alterative in diseases of the skin. In Europe it is said to be popularly used, in the form of gargle, in affections of the throat. The Indians of North America and the Canadians are reported to have employed the root with advantage in fevers. The plant may be given in substance, infusion, or decoction. The dose of the powder is a drachm or more.

AJUGA CHAMÆPITYS. *Ground Pine. Chamæpitys.* A low creeping, annual, labiate plant, a native of Europe, and found also in some parts of the United States. The leaves, which bear some resemblance to those of the pine in shape, have a strong, peculiar, resinous, not disagreeable odour, and a bitter, balsamic taste. They yield by distillation with water a small proportion of volatile oil, resembling that of turpentine. They are said to be stimulant, diuretic, and aperient; and have been given in rheumatism, gout, palsy, and amenorrhœa. The dose of the leaves in powder is one or two drachms; but their infusion in wine is considered the best preparation.

The *Ajuga reptans* or *common bugle*, and the *A. pyramidalis*, perennial plants of Europe, have also been used in medicine. They are nearly inodorous, but have a somewhat astringent, bitterish, and saline taste. Their virtues are probably those of a mild astringent and tonic. They have been recommended in pulmonary consumption, hæmoptysis and other hemorrhages, and in hepatic obstructions, and have enjoyed considerable reputation as vulneraries; but they are at present nearly obsolete.

ALCHEMILLA VULGARIS. *Ladies-mantle.* A perennial European herb, growing in meadows, on the banks of rivulets, and in the borders of woods. The whole plant has an astringent bitterish taste, which is strongest in the root. It was formerly employed in diarrhœa, and other complaints requiring the use of astringents. By the ancients it was highly esteemed; and extraordinary powers were ascribed to it by the alchemists, from whom, according to Linnæus, it derived its generic title.

ALCORNOCQUE. Under this name, a bark was introduced into Europe from South America, thirty or forty years since, and for a short time attracted considerable attention. It has been conjecturally referred by different writers to different plants, but its precise origin is unknown. In the Dictionary of Materia Medica of Merat and De Lens, it is described as being in large thick pieces, composed of two layers, of which the external is reddish, cracked, granular, spongy, and two or three lines in thickness, the internal lamellated, woody, and possessed of the property of imparting a yellow colour to the saliva when chewed. It is inodorous. The outer layer is of an astringent, somewhat bitter taste, and was thought to have febrifuge powers; the inner is much more bitter, and is decidedly emetic. The bark was brought into notice chiefly as a remedy in phthisis; but, failing to produce any favourable impression upon that complaint in the hands of European practitioners, it has fallen into entire neglect. It was given in the form of powder, in the dose of thirty grains; or half an ounce of it was boiled in a pint of water down to half a pint, and two or three table-spoonfuls of the decoction were administered every two hours. In these doses it acted as an emetic.

ALISMA PLANTAGO. *Water plantain.* A perennial herbaceous plant, common to Europe and the United States, and growing in streams, pools, ditches, and other standing waters. The root has when fresh an odour like that of Florentine orris, but loses it when dried. Its taste is acrid and nauseous. It acquired at one time considerable credit as a preventive of hydrophobia, for which purpose it was said to have been used with great advantage in Russia; but subsequent experiments have proved its total inefficacy. The Calmucks are said to use it for food. The leaves are rube-facient, and will sometimes even blister when applied to the skin. They have been recommended in gravel and complaints of the bladder, in the dose of a drachm.

ALKANET. This is the root of the *Anchusa tinctoria*, or *dyer's alkanet*, an herbaceous perennial plant, growing in the Grecian Archipelago and the South of Europe. The plant is said in some medical works to be cultivated abundantly in the South of France; but another plant is probably referred to—the *Lithospermum tinctorium* of Linnæus and De Candolle (the *Anchusa tinctoria* of Lamarck), which is a native of that country, and the root of which is considered as the true alkanet by the French writers.

Alkanet, as found in the shops, is in pieces three or four inches in length, from the thickness of a quill to that of the little finger, somewhat twisted, consisting of a dark-red, easily separable bark, and an internal ligneous portion, which is reddish externally, whitish near the centre, and composed of numerous distinct, slender, cohering fibres. As it comes to us it is usually much decayed internally, very light, and of a loose almost spongy texture. The fresh root has a faint odour, and a bitterish astringent taste; but when dried it is nearly inodorous and insipid. Its colouring principle, which abounds most in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a fine deep red; but is insoluble in water. It may be obtained separate by first exhausting the root with water, and then treating it with a weak solution of the carbonate of potassa or soda, from which the colouring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses decided acid properties, uniting with the alkalies and earths to form neutral compounds, which are of a blue colour, and have the singular property of being soluble in alcohol and ether. He calls it *anchusic acid*, and states that it is capable of being sublimed unchanged. (*Journ. de Pharm.* xix. 105.) The tincture of alkanet has its colour deepened by the acids, changed to blue by the alkalies, and again restored by neutralizing the latter substances. It may, therefore, be used as a test. The extract obtained by evaporating the tincture is dark brown.

Alkanet root is somewhat astringent, and was formerly applied to the treatment of several diseases; but it is now employed exclusively for colouring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. It is said also to be used in the preparation of spurious Port wine.

ALLIARIA OFFICINALIS. *Erysimum Alliaria*, Linn. *Hedge Garlic.* A perennial European herb, having when rubbed an odour like that of garlic, and of a bitterish somewhat acrid taste. When eaten it communicates an alliaceous smell to

the breath. The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and have been given in humoral asthma, chronic catarrh, and other complaints in which garlic is considered useful. The herb has also been recommended as an external application in gangrenous affections, and to promote suppuration.

ALNUS GLUTINOSA. *Common European Alder.* A European tree, of twenty-five feet or more in height, growing in swamps, on the sides of streams, and in other damp places. The bark and leaves are very astringent, and somewhat bitter. The former has been used in intermittent fever, the latter as a topical remedy in wounds and ulcers. The bruised leaves are sometimes applied to the breast for the purpose of repelling the milk. The cones also are said to be astringent, and to form a useful gargle in complaints of the throat. All these parts of the tree are used in dyeing, and the leaves and bark in tanning. The *Alnus serrulata*, or common *American alder*, has properties analogous to those of the European species.

AMBERGRIS. *Ambra grisea.* This substance, which is found floating on the sea, or thrown by the waves upon the shores of various countries, particularly in the southern hemisphere, is now generally believed to be produced in the intestines of the *Physeter macrocephalus* or spermaceti whale, and perhaps in those of some other fish. It is in roundish or amorphous pieces, usually small, but sometimes of considerable magnitude; and masses have been found weighing 50, 100, or even 200 pounds. These pieces are often composed of concentric layers. They are of various colours, usually gray, with brownish, yellow, and white streaks, often dark brown or blackish on the external surface. They are opaque, lighter than water, and of a consistence like that of wax. Ambergris has a peculiar aromatic agreeable odour, is almost tasteless, softens with the warmth of the hand, melts under 212°, is almost completely volatilizable by heat, and takes fire when heated in the open air. It is insoluble in water, but is readily dissolved, with the aid of heat, by alcohol, ether, and the volatile and fixed oils. It consists chiefly of a peculiar fatty matter analogous to cholesterol, and denominated by Pelletier and Caventou *ambrein*. This may be obtained by treating ambergris with heated alcohol, filtering the solution, and allowing it to stand. Crystals of ambrein are deposited. It differs from most other fatty matters in not forming soaps with the alkalies. When pure it has little or no odour. The other constituents of ambergris do not appear to have been thoroughly investigated. It is often adulterated; but does not then exhibit its ordinary fusibility and volatility. Ambergris was long regarded as a cordial and antispasmodic, somewhat analogous to musk in its mode of action; and has been recommended in typhoid fevers, and various nervous diseases. It formerly entered into a great variety of official preparations, and is still retained by some of the Pharmacopœias of the continent of Europe. It is, however, in all probability, very feeble in remediate power, and is much more used in perfumery than in medicine. The dose is from five grains to a drachm.

AMMONIO-TARTRATE OF IRON. *Ferri Ammonio-tartras.* This salt was first employed by Mr. Aikin, of London. According to Mr. Wm. Procter, Jr., of this city, it is best prepared by dissolving to saturation, freshly precipitated hydrated sesquioxide of iron in a solution of bitartrate of ammonia. The bitartrate may be made by saturating fifty drachms of tartaric acid, dissolved in a gallon of water, with carbonate of ammonia, and then adding fifty drachms of the acid to the solution formed. This is heated, by means of a water-bath, with the fresh hydrated sesquioxide, derived from fifty-three and a third drachms of U. S. subcarbonate of iron, dissolved in muriatic acid and precipitated by ammonia. The sesquioxide is dissolved, and a deep reddish-brown solution results, which is evaporated to dryness by means of a water-bath. This double salt, when prepared in small quantities, is in brilliant scales, dark-brown in mass, but garnet-red by transmitted light. When obtained in considerable quantities, it forms angular grains, resembling kino. It is very soluble in water, and has a strongly saccharine taste. Its aqueous solution undergoes no change by a boiling temperature. According to an analysis by Mr. Procter, it consists of one eq. of sesquioxide of iron, one of ammonia, two of tartaric acid, and four of water. (See Mr. Procter's paper in the *Am. Journ. of Pharm.* xii. 275.)

This salt has the general properties of the other ferruginous compounds. Its advantages are its ready solubility, palatable taste, and permanency. The dose is five grains or more, given in pill or solution. For a notice of the tartrate of protoxide of iron, see page 959.

ANACARDIUM OCCIDENTALE, Linn. *Cassuvium, pomiferum*, Lam. *Cashew-nut*. A small and elegant tree, growing in the West Indies, and other parts of tropical America. A gum exudes spontaneously from the bark, which bears some resem-

blance in appearance to gum Arabic, but is only in part soluble in water, and consists of proper gum and bassorin. It is the *gomme d'acajou*, of the French writers. The fruit is more important. It is a fleshy, pear-shaped receptacle, supporting at its summit, a hard, shining, ash-coloured, kidney-shaped nut, an inch or more in length, and three-quarters of an inch broad, consisting of two shells, with a black juice between them, and of a sweet oily kernel within the inner shell. The receptacle is of a red or yellow colour, and of an agreeable sub-acid flavour with some astringency. It is edible, and affords a juice which has been recommended as a remedy in dropsy. This juice is converted by fermentation into a vinous liquor, from which a spirit is obtained by distillation, much used in making punch, and said to be powerfully diuretic. The nuts are well known under the name of *cashew-nuts*. The black juice contained between their outer and inner shell, is extremely acrid and corrosive, producing when applied to the skin, severe inflammation, followed by blisters or desquamation of the cuticle. It is used in the West Indies for the cure of corns, warts, ringworms, and obstinate ulcers, and is said to be sometimes applied to the face by females in order to remove the cuticle, and produce a fresher and more youthful aspect. The worst case of external poisoning which has ever come under our notice, was produced in a lady who was exposed to the fumes of the nut while roasting. The face was so much swollen that for some time not a feature was discernible. The kernel, when fresh, has a sweet, agreeable taste, and is eaten like chestnuts, either raw or roasted. It is also used as an ingredient of puddings, &c., and forms an excellent chocolate when ground with cocoa. By age it becomes rancid and loses its agreeable flavour. The black juice of the nut, and a milky juice which flows from the tree by incision, are sometimes used for marking linen, upon which they leave a nearly indelible brown or black stain.

ANAGALLIS ARVENSIS. *Scarlet Pimpernel.* An annual plant, growing in Europe and this country, with small, delicate, procumbent stems, furnished with opposite branches, opposite ovate leaves, and small scarlet flowers, which are supported upon axillary, solitary peduncles, and appear in June and July. It is inodorous, and has a bitterish somewhat acrid taste. The ancients esteemed it a counter-poison, and in modern times it has been used as a preventive of hydrophobia; but at present no faith is placed in its alexipharmic powers. It is, nevertheless, not wholly inactive; as Orfila found three drachms of an extract prepared from it sufficient to destroy a dog, with marks of inflammation of the bowels. It has been recommended as a local application in old and ill-conditioned ulcers, and has been given internally in visceral obstructions, consumption, dropsy, epilepsy, mania, &c. But too little is known of its precise properties, to authorize its indiscriminate employment in these complaints. Another species, considered by Linnæus as a mere variety of the *A. arvensis*, is the *A. cærulea*, distinguished by its blue flowers. It is incorrectly designated by the older writers as the *female* plant, the former being called *male*. The medical properties of the two, so far as is known, are the same.

ANCHUSA OFFICINALIS. *Bugloss.* This species of *Anchusa* is a native of Europe, and unknown in the United States. It is a biennial plant, from one to three feet high, and was formerly much esteemed as a medicine. The root, leaves, and flowers, were all officinal. These are inodorous, and nearly tasteless. The root is mucilaginous and slightly sweetish, and the flowers very feebly bitter. The plant has no claim whatever to the credit, formerly attached to it, of possessing cordial and exhilarating properties. It was used by the ancients in hypochondriacal affections; but as it was given in wine, the elevation of spirits experienced may with propriety be ascribed to the vehicle. In France, the *Anchusa Italica*, which is there known as *buglosse*, is employed for the same purposes and in the same manner as the *Borago officinalis*.

ANDROMEDA ARBOREA. *Sorrel-tree.* A beautiful indigenous tree, growing in the valleys of the Alleghany mountains, from Pennsylvania to Florida. The leaves have a very pleasant acid taste, which has given rise to the common name of the tree. They are frequently used by hunters to allay thirst, and in decoction they form a grateful refrigerant drink in fevers.

The other species of *Andromeda* are shrubs, and some of them are ornamental. Dr. Barton, in his "Collections," states that a decoction of the *A. Mariana* is usefully employed in the Southern States, as a wash in a disagreeable ulceration of the feet to which the negroes are liable. The powder upon the leaves and buds of the *A. speciosa* is said to be a powerful errhine.

ANEMONE PRATENSIS. *Meadow Anemone.* This plant enjoyed at one time considerable credit from the recommendation of Störck, who believed that he had found

it useful in amaurosis and other complaints of the eye, in secondary syphilis, and in cutaneous eruptions. The *A. Pulsatilla*, an analogous species, has been employed for similar purposes; and favourable reports have been made of its efficacy in obstinate diseases of the skin, and in whooping-cough. The preparation employed was an extract of the herbaceous part of the plant, which was given by Storck in the dose of one or two grains daily, gradually increased to twenty grains or more. In large doses it was found frequently to produce nausea and vomiting, or griping and looseness of the bowels, and sometimes acted as a diuretic. The species of *Anemone* above mentioned are European plants, and are not cultivated in this country. We have several native species, which, however, are not employed. One of them, the *A. nemorosa*, which is common to Europe and the United States, is said to act as a poison to cattle, producing bloody urine and convulsions. It is stated also to have proved, when applied to the head, a speedy cure for tinea capitis. Most of the species are, in the recent state, acrid and rubefacient, resembling in this respect other Ranunculaceae, to which family they belong. They contain a peculiar crystallizable principle, named *anemonin*, which is converted into *anemonic acid* by the action of alkalies. (*Annalen der Pharm.* xxxii. 276.)

ANIME. *Gum Anime.* The substance known at present by the name of *anime*, is a resin supposed to be derived from the *Hymenaea Courbaril*, a tree of South America; though this origin is denied by Hayne, and is at least doubtful. It is in small, irregular pieces, of a pale lemon-yellow colour, sometimes inclining to reddish, more or less transparent, covered with a whitish powder, brittle and pulverizable, with a shining fracture, a weak but agreeable odour, and a mild resinous taste. It softens in the mouth, adheres to the fingers when in the state of powder, and readily melts with heat, diffusing its agreeable odour in an increased degree. It consists of two distinct resins, one soluble, the other insoluble in cold alcohol, and of a small proportion of volatile oil. There is a variety of a darker colour, less transparent, and exhibiting small cavities in the interior; in other respects resembling the preceding. Another variety of anime is the East Indian, supposed to be derived from the *Vateria Indica*; but this never reaches us as a distinct article of commerce. Anime formerly entered into the composition of various ointments and plasters; but is now used only as incense, or in the preparation of varnishes. The Brazilians are said to employ it internally in diseases of the lungs.

ANNOTTA. *Orleana.* The colouring substance called *annotta*, *arnotta*, or *roucou*, is the reddish pulp surrounding the seeds in the fruit of the *Bixa Orellana*, a middling sized tree growing in Guiana, and other parts of South America. The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to stand till the undissolved portion subsides. The water is then poured off, and the mass which remains, having been sufficiently dried, is formed into flat cakes or cylindrical rolls, and sent into the market. Annotta is of a brownish-red colour, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odour, and a rough, saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow colour, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. The chief uses to which it is applied, are for dyeing silk and cotton orange-yellow, and for colouring cheese. The colour, however, which it imparts to cloth is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is occasionally used to colour plasters, and has sometimes been substituted for saffron. It is said to be sometimes largely adulterated; and red ochre, powdered bricks, and colcothar have been employed for the purpose. If these substances be present, they will be left behind when the annotta is burned.

ANTHRISCUS CEREFOLIUM. De Cand. *Chærophyllum sativum*. Lam. *Scandix Cerefolium*. Linn. *Chervil*. An annual European plant, cultivated in gardens as a pot-herb, and supposed by some physicians to possess medicinal powers. It has a strong agreeable odour, especially when rubbed, and a pungent slightly bitterish taste. These properties it owes to a volatile oil, which may be separated by distillation with water. It is said to be deobstruent, diuretic, and emmenagogue, and has been recommended by different authors in consumption, scrofula, dropsy, cutaneous and scorbutic affections, and as an external application to swollen breasts, bruises, and other local complaints or injuries. It is, however, a very feeble remedy, and is more employed as an addition to broths than as a medicine.

ANTIRRHINUM LINARIA, Linn. **LINARIA VULGARIS**, Lindley. *Common Toadflax*. This species of *Antirrhinum* is a perennial herbaceous plant, from one to

two feet high, with numerous narrow linear leaves, and a terminal crowded spike of large yellow flowers. It is a native of Europe, but has been introduced into this country, where it is now naturalized, and grows in great abundance along the road sides, throughout the Middle States. It is readily distinguishable by the shape of its leaf, and by its conspicuous yellow flowers, which appear in succession from June to October. The herb is the part used. It should be collected when in flower, dried quickly, and kept excluded from the air. When fresh it has a peculiar, heavy, rather disagreeable odour, which is in a great measure dissipated by drying. The taste is herbaceous, weakly saline, bitter, and slightly acrid. This plant is said to be diuretic and cathartic, and has been used in dropsy, jaundice, and various cutaneous eruptions. It is most conveniently employed in the state of infusion. The fresh plant is sometimes applied externally, in the shape of poultice or fomentation, to hemorrhoidal tumours, and an ointment made from the flowers has been employed for the same purpose, and also as a local application in diseases of the skin.

AQUA BINELLI. An Italian nostrum, named after a physician of Turin, which at one time enjoyed great reputation in Europe as a styptic; but has been proved to possess very little efficacy. It was a transparent liquid, with little taste and an empyreumatic odour, and, after the discovery of creasote, was conjectured to contain a small proportion of that principle. It is now out of use.

AQUILEGIA VULGARIS. *Columbine.* A perennial herbaceous plant, indigenous in Europe, but cultivated in our gardens as an ornamental flower. All parts of it have been medicinally employed. The roots, leaves, and flowers have a disagreeable odour, and a bitterish, acrid taste. The seeds are small, black, shining, inodorous, and of an oleaginous sweetish taste, followed by a sense of acrimony. Columbine has been considered diuretic, diaphoretic, and antiscorbutic, and has been employed in jaundice, in small-pox to promote the eruption, in scurvy, and externally as a vulnerary. It is not used at present, and is even suspected to possess dangerous properties, like most other plants of the natural order of Ranunculaceæ to which it belongs.

ARECA NUT. *Betel Nut.* This is the product of the Areca Catechu, an East India tree belonging to the family of palms. The fruit, which is about the size and shape of a small egg, and of an orange-yellow colour, contains the nut embedded in a fibrous fleshy envelope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, which is the betel-nut of commerce, is of a roundish-conical shape, rather larger than a chestnut, externally of a deep-brown, diversified with a fawn colour, so as to present a reticular appearance, internally brownish-red with whitish veins, very hard, of a feeble odour when broken, and of an astringent, somewhat acrid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin, and various saline substances. It yields its astringency to water; and, in some parts of Hindostan, an extract is prepared from it having the appearance and properties of catechu. Immense quantities are consumed in the East, mixed with the leaves of the Piper Betel, and with lime, forming the masticatory so well known by the name of *betel*. The red colour which this mixture imparts to the saliva and the excrements is owing to the Areca nut, which is also powerfully astringent, and, by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. The nut is used in this country almost exclusively in the preparation of tooth-powder, for which purpose it is first reduced by heat to the state of charcoal. The superiority of this form of charcoal over that from other sources is probably owing to the extreme hardness of its particles.

ARSENATE OF AMMONIA. *Ammonix Arsenias.* This salt is obtained in crystals by saturating a concentrated solution of arsenic acid with ammonia or carbonate of ammonia, and allowing it to evaporate spontaneously. It has been used with advantage by Bielt, as an internal remedy, in several inveterate diseases of the skin. It is given in solution, formed by dissolving a grain of the salt in a fluidounce of distilled water. Of this the dose is from twenty to twenty-five drops, given in the course of the day, and gradually increased.

ARSENATE OF IRON. *Ferri Arsenias.* This salt may be formed by double decomposition, by adding a solution of sulphate of iron to one of arseniate of soda. It precipitates in the form of a dirty-green powder. It has been used by Carmichael, diluted with four times its weight of phosphate of iron, as a caustic application to cancerous ulcers. It may be made into ointment by being mixed with twelve times its weight of spermaceti cerate. Internally it has been given in cancerous affections, in the form of pill, in the dose of a sixteenth of a grain, three times a day.

ASPARAGUS OFFICINALIS. *Asparagus.* This well known plant, so abundantly cultivated as a garden vegetable, is a native of Europe. It is perennial and herbaceous. The *root*, which is inodorous, and of a weak sweetish taste, was formerly used as a diuretic, aperient, and purifier of the blood; and it is stated to be still employed to a considerable extent in France. It is given in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts that, in the dried state, it is wholly inert. The *young shoots*, as every one knows, are much used in spring as an article of diet. Before being boiled they have a disagreeable taste; and their juice was found by Robiquet and Vauquelin to contain a peculiar crystallizable principle, called *asparagin* (see p. 76), which, however, is not known to exert any special influence on the system. The sprouts themselves are not without effect, as the urine acquires a disagreeable odour very soon after they have been eaten. They are considered by some writers as diuretic, aperient, and deobstruent, and as constituting a very wholesome and useful article of diet, early in the spring, when so few vegetables are to be obtained. Broussais thought that they exerted a sedative influence over the heart, and recommended them especially in hypertrophy and other diseases of that organ attended with excessive action, and without phlogosis of the stomach. M. Gendrin, however, after much experience with asparagus, affirms that he has never found it to exercise the slightest influence over the actions of the heart, and ascribes its palliative effects in diseases of that organ, to its diuretic action. From the experiments of M. Gendrin it appears, that this medicine operates powerfully on the kidneys. He found it, in all the cases in which he administered it, to increase the quantity of urine, which, in some instances was quintupled. The most convenient forms for exhibition are those of syrup and extract, prepared from the shoots. The former may be given in the dose of one or two fluidounces, the latter of half a drachm or a drachm. The syrup may be made by adding a sufficient quantity of sugar to the expressed juice of the shoots, previously deprived of its albumen by exposure to heat and by filtration; the extract, by evaporating the same juice to the consistence of a pilular mass. The *berries* are capable of undergoing the vinous fermentation, and affording alcohol by distillation. In their unripe state they possess the same properties as the shoots, and probably in a much higher degree. We have employed a syrup prepared from them, with apparent advantage, in a case of diseased heart.

ASPLENIUM FILIX FEMINA. R. Brown. *Female Fern.* This is the *Polypodium Filix femina* of Linn, the *Aspidium Filix femina* of Swartz, and the *Athyrium Filix femina* of Roth. It has a root analogous in character to that of the male fern (*Aspidium Filix mas*), and has been supposed to possess similar vermifuge properties. At present, however, it is not used. The vulgar name of *female fern* has also been bestowed upon the *Pteris aquilina*, or *common brake*, which is asserted by some authors to have the property of destroying the tape-worm. The leaves of two species of Asplenium, the *A. Trichomanes* or *common spleenwort*, and *A. Adiantum-nigrum*, or *black spleenwort*, are somewhat mucilaginous, and have been used as substitutes for the *Maidenhairs* (*Adiantum Capillus Veneris* and *A. pedatum*) as pectorals, though destitute of the aromatic flavour, which is, perhaps, the chief recommendation of these plants.

BALM OF GILEAD. *Balsam of Gilead.* *Balsamum Gileadense.* *Baume de la Mecque*, Fr. The genuine balm of Gilead is the resinous juice of the *Amyris Gileadensis* of Linn., the *Balsamodendron Gileadense* of Kunth, a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and still retains its value in the estimation of the eastern nations, among whom it is employed both as a medicine and cosmetic. In western Europe, and in this country, it is seldom found in a state of purity, and its use has been entirely abandoned. It is described as a turbid, whitish, thick, gray, odorous liquid, which becomes solid by exposure. It possesses no medical properties which do not exist in other balsamic or terebinthinate juices. It was formerly known by the name of *opobalsamum*; while the dried twigs of the tree were called *xylobalsamum*, and the dried fruit, *carpobalsamum*.

BALSAM OF SULPHUR. This name was formerly given to a substance resulting from the reaction of sulphur upon olive oil at a high temperature. It was directed in the old Edinburgh Pharmacopœia, under the name of *Oleum Sulphuratum*; but was discharged from that work at the late revision. The directions of the College were to boil *eight parts* of olive oil and *one part* of sublimed sulphur together, with a gentle fire, in a large iron pot, stirring them constantly till they unite. The iron pot should be large enough to hold three times the quantity of the materials employed, as

the mixture might otherwise boil over. As the vapours which rise are apt to take fire, a lid should be at hand to cover the pot, and thus extinguish the flame if necessary. Sulphur is soluble to a considerable extent in heated oil, from which, if the solution be saturated, it is deposited in a crystalline state on cooling. But it is not a mere solution which this process is intended to effect. The oil is partly decomposed, and the resulting preparation is an extremely fetid, acrid, viscid, reddish-brown fluid. In order that it may be obtained, the oil must be heated to the boiling point. *Sulphurated oil* or *balsam of sulphur* was formerly thought useful in chronic catarrh, consumption, and other pectoral complaints; but inconvenience has arisen from its acrid properties, and its internal use has been abandoned. It is said to be sometimes applied as a stimulant to foul ulcers. The dose is from five to thirty drops.

BAPTISIA TINCTORIA. *Sophora tinctoria*, Linn. *Podalyria tinctoria*, Michaux. *Wild indigo*. This is an indigenous perennial plant, found in all parts of the United States, growing abundantly in woods and dry barren uplands. It is from one to three feet high, with a smooth, very branching stem, small, ternate, cuneate-obovate, bluish-green leaves, and yellow flowers, which appear in July and August, and, like the whole plant, become black when dried. The root, which is the part most highly recommended, is of a dark-brown colour, inodorous, and of a nauseous, somewhat acrid taste. Its virtues appear to reside chiefly in the cortical portion. In large quantities, it is said to operate violently as an emetic and cathartic; but in smaller doses, it produces only a mild laxative effect. Its general influence upon the system has not been accurately investigated. It is said to have proved useful in scarlatina, typhus fever, and in that state of system which attends gangrene or mortification. Dr. Thacher speaks highly of its efficacy as an external application to obstinate and painful ulcers; and Dr. Comstock, of Rhode Island, found it extremely useful, both as an internal and external remedy, in threatened or existing mortification. By the latter physician it was given in decoction, made in the proportion of an ounce of the root to a pint of water, of which half an ounce was administered every four or eight hours, any tendency to operate on the bowels being checked with laudanum. It may be used externally in the form of decoction or cataplasm. The stem and leaves are said to possess the same virtues as the root, though in a less degree. A pale blue colouring substance has been prepared from the plant as a substitute for indigo, but is greatly inferior.

BASSORA GUM. We are wholly ignorant of the plant which yields this substance. It came into commerce originally from the neighbourhood of Bassora, on the Gulf of Persia, but is frequently found mixed with gum brought from other countries, and is probably not the product of one plant exclusively. It is in irregular pieces, of various sizes, never very large, white or yellow, intermediate in the degree of its transparency between gum Arabic and tragacanth, inodorous, tasteless, and possessed of the property of yielding a slight sound when broken under the teeth. But a small portion of it is soluble in water, whether hot or cold. The remainder swells up considerably, though less than tragacanth, and does not, like that substance, form a gelatinous mass, as it consists of independent granules which have little cohesion. The soluble portion is pure gum, or as it is now sometimes named *arabin*; and, according to M. Guérin, constitutes 11·2 per cent. The insoluble portion consists of a peculiar principle called *bassorin*, associated with a small proportion of various saline substances, which yield, when the gum is burnt, 5·6 per cent. of ashes. The gum is useless both in medicine and pharmacy, and is described here only as an object to be avoided, and as affording a principle which enters into the composition of several officinal substances, and the nature of which, therefore, should be known.

Bassorin is insoluble in water, alcohol, and ether, but softens and swells up in hot or cold water. Diluted nitric and muriatic acids, with the aid of heat, dissolve it almost entirely. The acidulous solution, concentrated by evaporation, and treated with alcohol, lets fall a flocculent precipitate which has all the characters of pure gum, into which the *bassorin* appears to have been converted by the action of the acid. This does not, however, constitute more than a tenth part of the *bassorin* dissolved. By gradually evaporating the alcoholic acidulous solution, a thick bitterish liquid is obtained, which exhales a strong odour of ammonia when treated with potassa. Strong nitric acid converts *bassorin* into mucic and oxalic acids; and, treated with sulphuric acid, it yields a sweet crystalline substance which is incapable of the vinous fermentation. (Guérin.) Vauquelin was the first to call attention to this principle, upon which he conferred its present name, from having first observed it in the Bassora gum. Buchholz afterwards discovered the same or a closely analogous

principle in tragacanth; and John, a principle which was supposed to be the same, in the gum of the cherry tree; hence it has sometimes been called *tragacanthin* and *cerasin*. M. Guérin, however, has demonstrated that the insoluble principle of the cherry gum is essentially different from bassorin. Berzelius considers the latter as belonging to the class of substances which he associates together under the name of mucilage, and of which examples are furnished in the mucilages of flaxseed and of quince seed. For his views on this subject the reader is referred to the article *Linum*, in the first part of the work.

BDELLIUM. This name has been given to two different gum-resins, distinguished as *Indian* and *African bdellium*. Dr. Royle was informed that the former was obtained from the *Amyris Commiphora* of Roxburgh, growing in India and Madagascar. The latter is said to be the product of the *Heudelotia Africana*, which grows in Senegal. Bdellium sometimes comes mixed with gum Arabic and gum Senegal. It is either in small roundish pieces, of a reddish colour, semi-transparent, and brittle with a wax-like fracture, or in larger irregular lumps, of a dark brownish-red colour, less transparent, somewhat tenacious, and adhering to the teeth when chewed. It has an odour and taste like those of myrrh, but weaker. It is infusible and inflammable, diffusing while it burns a balsamic odour. According to Pelletier it consists of 59 per cent. of resin, 9.2 of gum, 30.6 of bassorin, and 1.2 of volatile oil including loss. In medical properties it is analogous to myrrh, and was formerly used for the same purposes; but it is now scarcely ever given internally. In Europe, it is still occasionally employed as an ingredient in plasters. The dose is from ten to forty grains.

BEAN OF SAINT IGNATIUS. *Faba Sancti Ignatii*. This is the product of the *Ignatia amara* of the younger Linnæus, which is now generally considered by botanists a species of *Strychnos*, and entitled *S. Ignatia*. (See *Nux Vomica*.) It is a tree of middling size, with numerous long, cylindrical, glabrous, vine-like branches, which bear opposite, nearly sessile, oval, pointed, entire, and very smooth leaves. The flowers are white, tubular, fragrant, and arranged in short axillary racemes. The fruit is of the size and shape of a pear, with a smooth, whitish, ligneous rind, enclosing about twenty seeds embedded in a dry pulpy matter, and lying one upon the other. These seeds are the part used. The tree is a native of the Philippine Islands, where the seeds were highly esteemed as a medicine, and, having attracted the attention of the Jesuits, were honoured with the name of the founder of their order.

They are about an inch long, rather less in breadth, still less in thickness, convex on one side, obscurely angular with two, three, or four faces on the other, and marked at one end with a small depression indicating their point of attachment. They are externally of a pale brown colour, apparently smooth, but covered in fact with a short down or efflorescence, which may be removed by scraping them with a knife. They are somewhat translucent, and their substance is very hard and horny. They have no smell, but an excessively bitter taste. To Pelletier and Caventou they afforded the same constituents as the *nux vomica*, but a much larger proportion of strychnia. (See *Nux Vomica*.) One thousand parts contain twelve of this alkali.

MM. Magendie and Delile have proved that they act on the human system in the same manner as the *nux vomica*. In the Philippines they have been employed for the cure of obstinate intermittents, and in numerous other diseases. It is probable that in small doses they act as a tonic. In this country they are never employed; nor have they a place in the British Pharmacopœias. We have introduced them here on account of their comparatively large proportion of strychnia, which is triple that contained in the *nux vomica*. In France they are profitably employed for the extraction of this principle.

BEDEGUAR. *Fungus Rosarum*. An excrescence upon the sweet briar or *eglan-tine*, and upon other species of *Rosa*, produced by the puncture of several insects, especially by one or more species of *Cynips*. It is of an irregular, usually roundish shape, about an inch in diameter, having numerous cells internally, in each of which is the larva of an insect. It has little smell, and a slightly astringent taste, and probably contains tannic acid. Though formerly considered diuretic, anthelmintic, and lithontriptic, and employed as a remedy for toothache, it has fallen into entire disuse. It was given in doses of from ten to forty grains.

BENZOIN ODORIFERUM. Nees. *Laurus Benzoin*. Linn. *Spice-wood*. *Spice-bush*. *Fever-bush*. An indigenous shrub, from four to ten feet high, growing in moist, shady places, in all parts of the United States. Its flowers appear early in spring, long before the leaves, and are succeeded by small clusters of oval berries, which when ripe, in the latter part of September, are of a shining crimson colour. All parts of the shrub have a spicy, agreeable flavour, which is strongest in the bark and ber-

ries. The small branches are sometimes used as a gently stimulant aromatic, in the form of infusion or decoction. They are said to be employed in this way by the country people as a vermifuge, and an agreeable drink in low fevers. Dr. William Barton says that the bark, as he has been informed, is extensively used in the country, and with much success, in intermittents. The berries, dried and powdered, were sometimes substituted, during the revolutionary war, for allspice. According to Dr. Drake, the oil of the berries is used as a stimulant.

BERBERIS VULGARIS. *Barberry.* A shrub growing wild in Europe and the United States, and sometimes cultivated in gardens on account of its berries. These grow in loose bunches, are oblong and of a red colour, have a grateful, sour, astringent taste, and contain malic and citric acids. They are refrigerant, astringent, and antiscorbutic, and are sometimes used in Europe, in the form of drink, in febrile diseases and diarrhœas. An agreeable syrup is prepared from the juice; and the berries themselves are sometimes preserved for the table. The root and inner bark have been used for dyeing yellow, and are said to have been employed beneficially in jaundice. They owe their colouring property to a peculiar crystallizable principle, which has been denominated *berberin*, and which is said, in the dose of from one to ten grains, to act as a tonic and purgative. (*Journ. de Pharm.* xxi. 309.) It is a vulgar error to suppose that the vicinity of this plant is very injurious to wheat. The American plant differs slightly from the European, and is described by Pursh as a distinct species, under the name of *B. Canadensis*. It grows in mountains and hilly districts from Canada to Virginia. The berries are smaller and much less juicy than those of the garden barberry.

BETONICA OFFICINALIS. *Wood betony.* A perennial European herb, belonging to the natural order of labiate plants, the general properties of which it possesses in some degree. It has a pleasant but feeble odour, and a warm, somewhat astringent, and bitterish taste. By the ancients it was very highly esteemed, and employed in numerous diseases; but it is at present little used. It appears to be slightly warming and corroborant, but is inferior in this respect to many other plants belonging to the same family. The root has been considered emetic and purgative.

BETULA ALBA. *Common European birch.* Various parts of this tree have been applied to medical uses. The *inner bark*, which is bitterish and astringent, has been employed in intermittent fever. The epidermis is separable into thin layers, which may be employed as a substitute for paper, and are applied to various economical uses. The bark contains a peculiar principle, called *betulin*, which is obtained by first exhausting it with boiling water, then treating it with boiling alcohol which deposits impure betulin upon cooling, and finally purifying the deposited matter by repeated solutions and crystallizations in ether. (*Annal. der Pharm.* xxix. 135.) Betulin is white, uncrystallizable, fusible at about 400°, sublimable, insoluble in water, and soluble in hot alcohol and in ether. In the fused state it emits the peculiar odour of heated birch bark, and when sublimed is apt to suffer partial decomposition. It consists of carbon, oxygen, and hydrogen, and is ranked among the subresins. The bark, when distilled, affords an empyreumatic volatile oil, having the peculiar odour of Russia leather, in the preparation of which it is employed. The *leaves*, which have a peculiar, aromatic, agreeable odour, and a bitter taste, have been employed in the form of infusion, in gout, rheumatism, dropsy, and cutaneous diseases. The same complaints, particularly dropsy, are said to have been successfully treated by enveloping the body in the fresh leaves, which thus applied excite perspiration. When the stem or branches of the tree are wounded, a sweet *juice* flows out, which is considered useful in complaints of the kidneys and bladder. In consequence of the sugar it contains, it is susceptible, upon the addition of yeast, of the vinous and subsequently of the acetous fermentation. A beer, wine, vinegar, and spirit are prepared from it, and habitually used in some parts of Europe.

Of the American species of birch, the *Betula lenta*, variously called *sweet birch*, *black birch*, *cherry birch*, and *mountain mahogany*, is remarkable for the aromatic flavour of its bark and leaves, which have the odour and taste of the *Gaultheria procumbens*, and are sometimes used in infusion, as an agreeable, gently stimulant, and diaphoretic drink. This species also affords a saccharine liquor, which, indeed, appears to be common to all the birches. The bark of the *B. papyracea* very closely resembles that of the common European birch, and is much employed by the Northern Indians for making canoes. Thin layers of the epidermis may be advantageously placed inside of boots to prevent the access of moisture.

BEZOAR. This name has been applied to concretions which form in the stomach or intestines of animals, and which were at one time thought to possess extraordinary

medical virtues. Numerous varieties have been noticed; but they were arranged in two classes, the *oriental bezoars* (*Lapis bezoar orientalis*), and *western bezoars* (*lapis bezoar occidentalis*), of which the former were most highly esteemed. They have fallen into merited neglect.

BIRD-LIME. A viscid substance existing in various plants, particularly in the bark of the *Viscum album*, and *Ilex aquifolium* or European holly, from the latter of which it is usually procured. The process for preparing it consists in boiling the middle bark for some hours in water, then separating it from the liquid, and placing it in proper vessels in a cool situation, where it is allowed to remain till it becomes viscous. It is then washed to separate impurities, and constitutes the substance in question. Bird-lime thus prepared is greenish, tenacious, of a glutinous consistence, of a bitterish taste, and of an odour analogous to that of flaxseed oil. Exposed to the air in thin layers it becomes dry, brown, and pulverizable, but re-acquires its viscosity upon the addition of water. It consists of several proximate principles, but is thought to owe its characteristic properties to the presence of a peculiar substance, identical with that which exudes spontaneously from certain plants, and which has received the name of *glu* from the French chemists. This principle is without odour or taste, extremely adhesive, fusible by heat, inflammable, insoluble in water, nearly insoluble in alcohol, but dissolved freely by sulphuric ether, and the oil of turpentine. According to M. Macaire, it is insoluble in the fixed oils, either hot or cold. This property distinguishes it from the resins, to which Berzelius is disposed to attach it. M. Macaire proposes for it the name of *viscin*. (*Journ. de Pharm.* xx. 18.) Bird-lime is so tenacious, that it may be employed to catch small birds, which, when they alight on a stick thickly covered with it, are unable to escape.

BISULPHURET OF CARBON. *Carburet of Sulphur.* This compound, discovered by Lampadius in 1796, is formed by passing the vapour of sulphur over fragments of charcoal heated to redness in a porcelain tube. It is a transparent, colourless, exceedingly volatile liquid, having a pungent, somewhat aromatic taste, and a very fetid smell. Its sp. gr. is 1.272. In composition it is a bisulphuret. It was formerly employed in obstinate rheumatic and arthritic affections, in paralysis and cutaneous eruptions, and more recently as a solvent in indolent tumours. It is used both internally and externally. For internal exhibition in gout and rheumatism, Dr. Otto, of Copenhagen, employed an alcoholic solution, in the proportion of two drachms to the fluidounce, of which four drops were given every two hours. At the same time the affected parts were rubbed with a liniment, made by dissolving the bisulphuret in the same proportion in olive oil. Dr. Krimer applied it to an indolent tumour, by allowing forty or fifty drops to fall upon it three times a day. This treatment, which may be supposed to act by the cold produced, assisted by the internal use of animal charcoal and cicuta, and the employment of warm alkaline baths, was attended with success. He also succeeded in reducing several strangulated herniæ, by applying some drops of the bisulphuret to the hernial tumour. (*Amer. Journ. of Pharm.* ix. 264, from the *Journ. de Pharm.*)

BOLE ARMENIAN. The term *bolus* or *bole* was formerly applied to various forms of argillaceous earth, differing in their colour, or place of origin. Thus we find mentioned, among others, the *Armenian*, *Lemnian*, and *French boles*, and the *red* and *white boles*. Some of these substances were so highly valued as to be formed into small masses and impressed with a seal, and hence received the name of *terræ sigillatæ*. They were all similar in effect, though the small proportion of oxide of iron contained in the coloured boles may have given them greater activity. The only one at present kept in the shops is that called *bole Armenian*, from its resemblance to the substance originally brought from Armenia. It is prepared by trituration and elutriation from certain native earths existing in different parts of Europe. It is in pieces of various sizes, of a reddish colour, soft and unctuous to the touch, adhesive to the tongue, and capable of mixing with water so as to form a paste. It consists chiefly of alumina and silica, coloured with oxide of iron. The boles were formerly employed as absorbent medicines and astringents; and they were undoubtedly useful in some cases of acidity of the stomach and relaxed bowels; but they have been superseded by more active medicines. The *bole Armenian* is now used chiefly as an ingredient in tooth powders.

BORAGO OFFICINALIS. *Borage.* This is an annual, hairy, succulent European plant, one or two feet high, with fine blue flowers, on account of which it is sometimes cultivated in our gardens. All parts of it abound in mucilage, and the stem and leaves contain the nitrate of potassa with other saline ingredients. To these constituents the plant owes all its virtues. It is much used in France. An infusion

of the leaves and flowers, sweetened with honey or syrup, is employed as a demulcent, refrigerant, and gently diaphoretic drink in catarrhal affections, rheumatism, diseases of the skin, &c. The expressed juice of the stem and leaves is also given in the dose of from two to four ounces. The flowers are sometimes applied externally as an emollient. A distilled water, extract, and syrup were formerly used, but have fallen into neglect. Borage is scarcely known in this country as a medicinal plant, and is altogether too feeble to merit much attention.

BRAZIL WOOD. A red dye-wood, the product of different species of *Cæsalpina*, growing in the West Indies and South America. Two varieties are known in commerce:—1. the proper Brazil-wood, said to be derived from the *Cæsalpina echinata*, and sometimes called *Pernambuco* or *Fernambuca wood*, from the province of Brazil, where it is collected; 2. the *brasileto*, produced by the *C. Braziliensis* and *C. Crista*, which grow in Jamaica and other parts of the West Indies. The former is the most highly valued. The *sappan* or *sampfen wood* may be referred to the same head, being obtained from the *Cæsalpina Sappan*, and possessing properties analogous to those of the *brasileto*. The *Nicaragua* or *peach wood* is also analogous to the *brasileto*, and is said by Bancroft to be derived from a species of *Cæsalpina*. It is produced in the East Indies. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its colouring matter to water. It was formerly used in medicine; but has been abandoned as inert. In pharmacy it sometimes serves to colour tinctures, &c.; but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink.

BROMIDE OF IRON. *Ferri Bromidum*. This bromide is obtained by heating gently in thirty parts of water, two parts of bromine and one of iron filings. When the liquid becomes greenish, it is filtered and evaporated to dryness; and the dry mass, again dissolved and evaporated to dryness, furnishes the bromide. Bromide of iron is a brick-red deliquescent salt, very soluble, and extremely styptic. It is employed as a tonic and resolvent, and given in the dose of a grain twice a day, in the form of pill, made up with conserve of roses and gum Arabic. It is formed as the first step of the process for preparing the officinal bromide of potassium.

BROMIDES OF MERCURY. The *protobromide* is formed by adding bromide of potassium to nitrate of protoxide of mercury. It falls as a white curdy precipitate. The *bibromide* may be obtained by digesting the protobromide with water containing bromine. It is in the form of colourless crystals, soluble in water and alcohol. Exposed to heat it enters into fusion and sublimes. Both these bromides are analogous in composition and medicinal properties to the corresponding iodides of mercury. (See pages 992 and 993.) The protobromide is given in the dose of a grain daily, gradually increased. The bibromide, like corrosive sublimate, is an irritant poison, and may be administered in doses of the sixteenth of a grain, gradually increased to a fourth, either in the form of pill, or in ethereal solution, made by dissolving a grain in a fluidrachm of ether.

BRYONY. *White Bryony*. This is the root of the *Bryonia alba* or white bryony, a perennial, climbing, herbaceous plant, growing in thickets and hedges, in different parts of Europe. It bears rough, heart-shaped, five-lobed leaves, small yellow monœcious flowers arranged in racemes, and roundish black berries about the size of a pea. Another species called *B. dioica*, with diœcious flowers and red berries, bears so close a resemblance in character and properties to the preceding, that it is considered by some botanists merely a variety. The roots of both plants are gathered for use. When fresh they are spindleshaped, sometimes branched, a foot or two in length, as thick as the arm, or even thicker, externally yellowish-gray and circularly wrinkled, within white, succulent, and fleshy, of a nauseous odour which disappears in great measure upon drying, and of a bitter, acrid, very disagreeable taste. The peasants are said sometimes to hollow out the top of the root, and to employ the juice which collects in the cavity as a drastic purge. (*Merat and De Lens*.) The berries of the plant are also purgative and are used in dyeing.

As kept in the shops, the root is in circular transverse slices, of a large diameter, externally yellowish-gray and longitudinally wrinkled, internally of a whitish colour becoming darker by age, concentrically striated, light, brittle, and readily pulverizable, yielding a whitish powder. A peculiar bitter principle called *bryonin* has been discovered in the root, but has not been isolated for practical purposes. It contains, besides, starch in considerable proportion, gum, resin, a concrete oil, albumen, and various saline substances. It yields its active properties to water.

Bryony is an active hydragogue cathartic, in large doses sometimes proving emetic, and disposed, if too largely administered, to occasion inflammation of the alimentary

mucous membrane. The recent root is highly irritant, and is said, when bruised and applied to the skin, to be capable of producing vesication. The medicine was well known to the ancients, and has been employed by modern physicians, but is now nearly superseded by jalap, which is more certain, and less liable to lose its strength by age. The dose of the powdered root is from a scruple to a drachm.

CAHINCA. Though not admitted into the Pharmacopœias, this medicine has attracted so much attention as to have just claims to notice in the present work. The name of *cahinca* or *cainca* was adopted from the language of the Brazilian Indians. The Portuguese of Brazil call the medicine *raiz pretta* or black root. When first noticed in Europe, it was supposed to be derived from the *Chiococca racemosa* of Linnæus, which was known to botanists as an inhabitant of the West Indies. But Martius, in his "Specimen Materiæ Medicæ Brasiliensis," describes two other species of Chiococca, the *C. anguifuga* and *C. densifolia*, which afford roots having the properties of that ascribed to the *C. racemosa*; and as the medicine is brought from Brazil, not from the West Indies, there is reason to believe that it is really derived from one or both of the plants named by that botanist. A. Richard, however, states that he has received from more than one source in Brazil, specimens of the *C. racemosa* as the *cahinca* plant; and it is not impossible that the roots of the three species possess identical properties and are indiscriminately used.

The *cahinca* root, as found in French commerce, is described by M. Achille Richard in the following terms. "It is of a reddish-brown colour and consists of cylindrical branches, two or three feet long, of the thickness of a quill or smaller, occasionally putting forth slender and branching fibres, obscurely striated longitudinally, presenting at certain distances small irregular tubercles, and here and there transverse fissures produced by drying. These branches are composed of a very thin whitish bark, covered externally with an adhering brown epidermis, and of an internal ligneous centre, which forms almost the whole mass of the root. The cortical portion, which is of a resinous character, has a bitter disagreeable taste, somewhat acrid and astringent; the ligneous part is quite tasteless. Together with the pieces just described, others are sometimes found, derived from the branches of the stem above ground, or from those which run along the ground and have taken root. They are distinguishable from the true root by being straighter and more regular, and presenting a medullary canal in their centre. The taste of their cortical portion is much weaker, and they are probably less active." (*Elem. d'Hist. Nat. Med.* ii. 331.)

A specimen brought into our market as the *cahinca*, consisted of cylindrical pieces, varying in size from the thickness of a straw to that of the little finger, somewhat bent or contorted, slightly wrinkled longitudinally, with occasional small asperities, internally ligneous, externally covered with a thin brittle reddish-brown bark, having a light brown or brownish ash-coloured epidermis. The virtues of the root reside almost exclusively in the cortical portion. They are extracted by water and alcohol. *Cahinca* has been analyzed by several chemists. Four distinct principles were discovered in it by Pelletier and Caventou:—1. a crystallizable substance, in which all the bitterness of the root resides; 2. a green fatty matter of a nauseous odour; 3. a yellow colouring matter; and 4. a coloured viscid substance. The crystallizable principle appears to be that in which the medical virtue resides. Under the belief that it is essentially acid, its discoverers have named it *cahincic acid*. It is white, without smell, of a taste at first scarcely perceptible, but afterwards extremely bitter and slightly astringent, of difficult solubility in water, but readily soluble in alcohol, permanent in the air, and unaltered at the temperature of boiling water. It reddens vegetable blues, and unites with the alkalies, but does not form crystallizable compounds. The form in which it exists in the root is thought to be that of a subcahincate of lime.

Medical Properties. *Cahinca* is tonic, diuretic, purgative, and emetic. In moderate doses it gently excites the circulation, increases the discharge of urine, and produces evacuations from the bowels; but is rather slow in its operation. Like most other diuretics, it may be so administered as to prove diaphoretic, by keeping the skin warm, using warm drinks, and counteracting its purgative tendency. In some patients it occasions nausea and griping pains in the bowels, and in very large doses always acts powerfully both as an emetic and cathartic. In Brazil it has long been used by the natives as a remedy for the poisonous effects resulting from the bites of serpents; and its Indian name is said to have been derived from this property. According to Martius, the bark of the fresh root is rubbed with water till the latter becomes charged with all its active matters; and the liquid, while yet turbid, is taken

in such quantities as to produce the most violent vomiting and purging, preceded by severe spasmodic pains. Patrick Brown speaks of the root of the *C. racemosa* as resembling seneka in taste, and as very useful in obstinate rheumatisms. But the virtues of cahinea in dropsy, though well known in Brazil, were first communicated to the European public in the year 1826, by M. Langsdorff, Russian Consul at Rio Janeiro. Achille Richard afterwards published a few observations in relation to it in the *Journal de Chimie Medicale*; and its properties were subsequently investigated by numerous practitioners. M. François of Paris contributed more than any other physician to its reputation as a cure for dropsy. It was considered by him superior to all other remedies in hydropic complaints. General experience appears to have been in its favour, but by no means to the extent of the partial estimate of Dr. François; and, having been found equally liable with other diuretics to the charge of uncertainty, it is now little used. It may be employed in substance, decoction, extract, or tincture. The powdered bark of the root may be given as a diuretic and purgative, in a dose varying from a scruple to a drachm; but in this form the remedy is considered very uncertain. The aqueous extract is usually preferred. The dose of this is from ten to twenty grains. An extract may also be prepared with diluted alcohol, and given in the same dose. Dr. François recommends that in the treatment of dropsy, a sufficient quantity should be given at once to produce a decided impression, which should afterwards be maintained by smaller doses, repeated three or four times in the twenty-four hours.

CALENDULA OFFICINALIS. *Marygold.* This well known garden plant was formerly much employed in medicine. It has a peculiar, rather disagreeable odour, which is lost by drying, and a bitter, rough, saline taste. Among its constituents is a peculiar principle, called *calendulin*, discovered by Geiger most abundantly in the flowers, and considered by Berzelius as analogous to bassorin, though soluble in alcohol. The plant was thought antispasmodic, sudorific, deobstruent, and emmenagogue, and was given in low forms of fever, scrofula, jaundice, amenorrhœa, and various other complaints. Both the leaves and flowers were used; but the latter were preferred, and were usually administered in the recent state, in the form of tea. An extract was also prepared, and employed with supposed advantage in cancerous and other ulcers, sick stomach, &c. At present marygold is very seldom if ever used in regular practice.

CALOTROPIS GIGANTEA. Brown. *Asclepias gigantea*, Linn. Under the name of *madar*, or *mudar*, a medicine has been employed in the East Indies, with great asserted advantage, in numerous complaints. It is the bark of the root of a species of Calotropis, which has been generally considered as the *C. gigantea*; but which is asserted by Dr. Casanova to be a distinct species, and has received from him the name of *C. Madarii Indico-orientalis*. The *C. gigantea* is a native of Hindostan, and has been introduced into the West Indies, where it is now naturalized. The bark, as employed, is destitute of epidermis, of a whitish colour, nearly or quite inodorous, and of a bitter, somewhat nauseous taste. It appears to have the general properties of many other acrid medicines; in small doses, increasing the secretions, and in larger, producing nausea and vomiting. According to Dr. Casanova, who published an essay upon the subject at Calcutta, it is more especially directed to the skin, the capillaries and absorbents of which it stimulates to increased action. It is chiefly recommended as a remedy in the obstinate cutaneous diseases of tropical climates, such as elephantiasis and leprosy. It has been employed also with advantage in syphilis, dropsy, rheumatism, and hectic fever. It is administered in substance in the dose of from three to twelve grains, three times a day, and gradually increased till it affects the system.

CAM WOOD. A red dye-wood, procured from the *Baphia nitida* of De Candolle, a leguminous tree, growing on the Western Coast of Africa. The wood is usually kept in the shops in the ground state.

CANARY SEED. The seeds of the *Phalaris Canariensis*, an annual plant, belonging to the family of grasses, originally from the Canary Islands, but now growing wild in Europe and the United States, and cultivated in many places. The seeds are ovate, somewhat compressed, about two lines long, shining and of a light yellowish-gray colour externally, and brownish within. Their chief constituent is starch. They were formerly esteemed medicinal, but are not now employed unless for the formation of emollient cataplasms. They are nutritive, and their meal is said to be mixed, in some places, with wheat flour, and made into bread. They are much used as food for Canary birds.

CANNABIS SATIVA. *Hemp.* An annual plant, originally from Asia, but now cultivated in various parts of Europe and North America. The *leaves* are possessed of narcotic properties, and are employed in Persia and the East Indies, in the form of infusion, as an intoxicating drink. They are also smoked, in these and other countries of the East, in the same manner as tobacco, with which they are frequently mixed. A resinous exudation from the plant is much employed for the same purpose. Even the odour of the fresh plant is stated to be capable of producing vertigo, headache, and a species of intoxication. According to Dr. O'Shaughnessy, of Calcutta, who has experimented with this narcotic, it alleviates pain, exhilarates the spirits, increases the appetite, acts decidedly as an aphrodisiac, produces sleep, and in large doses, occasions intoxication, a peculiar kind of delirium, and catalepsy. Its operation, in the hands of Dr. Pereira, appeared to resemble very much that of opium. (*Pereira's Mat. Med.*) Dr. O'Shaughnessy employed an alcoholic extract of the dried tops with great advantage in tetanus, and with alleviating effects in a fatal case of hydrophobia. He gave the remedy usually in doses of two or three grains, at intervals of two, three, or four hours; though, in these violent affections, the quantity may be much increased; and in hydrophobia from ten to twenty grains may be given at once. He employed the remedy also in rheumatism and cholera, giving, in the latter affection, ten drops every half hour, of a solution made with three grains of the extract and a drachm of proof spirit. (*Medical Examiner*, iii. 530.) The *seeds* of hemp have also been used in medicine. They are about the eighth of an inch long, roundish-ovate, somewhat compressed, of a shining gray colour, inodorous, and of a disagreeable, oily, sweetish taste. They contain a considerable quantity of fixed oil, which is separated by expression, and used to some extent in the arts. They contain also uncrystallizable sugar and albumen, and when rubbed with water afford an emulsion, which may be used advantageously in inflammatory affections of the mucous membranes, though it is not superior to a similar preparation from other emulsive seeds. They are much used as food for birds, which are fond of them. It is, however, for the fibrous bark of hemp, and the various products manufactured from it, that the plant is chiefly cultivated. Some consider the hemp cultivated in the East as specifically different from the common hemp; and name it *Cannabis Indica*; but most botanists think the two plants identical.

CAOUTCHOUC. *Gum elastic.* The substance known by this name in commerce is the concrete juice of the *Siphonia Caluchu* of Schreber and Willdenow, identical with the *Siphonia elastica* of Persoon, the *Jatropha elastica* of the younger Linnæus, and the *Hevea Guianensis* of Aublet. This is a large tree growing in Brazil, Guiana, and probably also in Central America. (*Journ. Phil. Col. of Pharm.* iii. 292.) On being wounded it emits a milky juice, which concretes on exposure, and constitutes the substance in question. A similar product is afforded by several other lactescent plants; but the juice of the *Siphonia* alone is extensively collected for use. Caoutchouc comes to us in different forms, sometimes in large flat pieces, sometimes in the shape of various animals, but usually in that of small flasks. These are formed by applying successive layers of the juice upon models of clay, which are broken and removed when the coating has attained a sufficient thickness and consistence. In the drying of these layers they are said to be exposed to smoke, which gives to the concrete mass a blackish colour. The juice, when it concretes by exposure to the air, assumes on the outer surface a yellowish-brown colour, while the mass remains white or yellowish-white within. The recent juice is not a pure proximate principle; but contains, according to Faraday, 1·9 per cent. of vegetable albumen, traces of wax, 7·13 per cent. of a bitter azotized substance soluble in water and alcohol, 2·9 of a substance soluble in water but insoluble in alcohol, 56·37 of water with a little free acid, and only 31·7 of the pure elastic principle to which chemists have given the name of caoutchouc. Some of these principles exist also in greater or less proportion in the concrete juice, which, as it reaches us, is usually contaminated with the soot derived from the smoke used in drying it. *Pure caoutchouc* is nearly colourless, and in thin layers transparent. It is highly elastic, lighter than water, without taste and smell, fusible at about 248°, remaining unctuous and adhesive upon cooling, inflammable at a higher temperature, insoluble in water, alcohol, the weak acids, and alkaline solutions, soluble in ether when entirely freed from alcohol, soluble also in most of the fixed and volatile oils, though at the expense of its elasticity. It is said, however, that the oils of lavender and sassafras dissolve it without change, and that when precipitated by alcohol from its solution in cajuput oil, it is still elastic. But its best solvent, for practical purposes, is an empyreumatic volatile oil obtained by the distillation of caoutchouc itself. Caoutchouc is not affected by common air, chlorine,

muriatic or sulphurous acid gas, nor by ammonia. It consists, according to Faraday, of 87.2 parts of carbon, and 12.8 of hydrogen.

Caoutchouc is used for erasing pencil marks; in the formation of flexible tubes for the laboratory, and of catheters and bougies for surgical purposes; in the melted state, as a luting to the joints of chemical apparatus; in the shape of thin layers, for covering the mouths of bottles, and for other purposes in which the exclusion of air and moisture is requisite; in the manufacture of water-proof cloth; and for numerous other objects, to which its elasticity, and the resistance which it offers to the ordinary solvents and to other powerful chemical agents peculiarly adapt it. Every one is aware of the highly important application which has recently been made of caoutchouc to the manufacture of water-proof shoes. It is most conveniently brought to the state of thin layers, in which it may often be used advantageously by the chemist and apothecary, by softening the small flasks in ether containing alcohol, or by boiling them in water for fifteen minutes, and then distending them by means of air forced into them. Tubes of caoutchouc may be made from its ethereal solution, or from the juice imported in the liquid state.

CAPPARIS SPINOSA. *Caper-bush.* A low, trailing shrub, growing in the South of Europe and North of Africa. The buds or unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acid burning taste, and is considered useful in scorbutic affections. The dried bark of the root was formerly officinal. It is in pieces partly or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acrid, and aromatic taste. It is considered diuretic, and was formerly employed in obstructions of the liver and spleen, amenorrhœa, and chronic rheumatism.

CARANNA. *Gum Caranna.* A resinous substance, in pieces of a blackish gray colour externally, dark-brown internally, somewhat shining and translucent, brittle and pulverizable when dry, but, in the recent state, soft and adhesive like pitch, easily fusible, of an agreeable balsamic odour when heated, and of a bitterish resinous taste. (*Geiger.*) It is said to be derived from the *Amyris Caranna* of Humboldt, a tree growing in Mexico and South America. *Geiger* refers it also to the *Bursera gummifera* of the West India Islands; but the resin obtained from this tree is described by the French writers under the name of *resine de Gomart*, or *resine de chibou* or *cachibou*, and is said to bear a close resemblance to the resin *tacamahac*.

CARBURET OF IRON. *Ferri Carburetum. Plumbago. Black Lead.* This substance has been used both internally and externally in herpetic and other cutaneous affections. For medicinal use it is reduced to very fine powder, and freed from impurities by being boiled with water, and digested with dilute nitro-muriatic acid. The dose is from five to fifteen grains or more, three or four times a day, given in the form of powder or pill. The ointment is made by mixing from two to six drachms of the carburet with an ounce of lard.

CATALPA CORDIFOLIA. *Bignonia Catalpa. Linn. Catalpa tree, or Catauba tree.* This is a beautiful flowering tree, growing wild in this country, and occasionally cultivated for ornamental purposes. It has been introduced into the gardens of Europe. It is commonly reputed to possess poisonous properties. The seeds have been advantageously employed by several practitioners of Continental Europe in asthma. *M. Automarchi* recommends a decoction made by boiling twelve ounces of water with three or four ounces of the seeds down to six ounces, the whole to be given morning and night. (*Journ. of the Phil. Col. of Pharm.* vi. 352.)

CEANOTHUS AMERICANUS. *New Jersey Tea. Red-root.* A small indigenous shrub, growing throughout the United States. The root is astringent, and imparts a red colour to water. It is said to be useful in syphilitic complaints, in which it is given in the form of decoction, made in the proportion of two drachms of the root to a pint of water. *Schoepf* states that it is purgative. The leaves were used during the revolutionary war as a substitute for tea. *Dr. Hubbard*, in a communication to the *Boston Medical and Surgical Journal*, (Sept. 30th, 1835,) speaks very highly of the use of the *Ceanothus* as a local application in aphthous affections of the mouth and fauces, and in the sorethroat of scarlatina, and as an internal remedy in dysentery. He used a strong infusion of the dried leaves and seeds.

CHELIDONIUM MAJUS. *Celandine.* A perennial herbaceous plant, growing wild in this country, about old houses and in rocky places; but supposed to have been introduced from Europe, where it is indigenous. It is one or two feet high, bears pinnate leaves and small peduncled umbels of yellow flowers, and, when wounded, emits

a yellow, opaque juice. It was employed by the ancients, and is occasionally used in modern practice, but little on this side of the Atlantic. The whole plant is used. It has a faint unpleasant odour, and a bitter, acrid, durable taste, which is stronger in the roots than in the leaves. The odour is nearly lost by drying, but the taste remains. The yellow juice is bitter and exceedingly acrid, and when applied to the skin produces inflammation and even vesication. The plant, analyzed by MM. Chevallier and Lassaigne, afforded a bitter resinous substance of a deep yellow colour; a kind of gum-resin of an orange-yellow colour, and bitter, nauseous taste; mucilage; albumen; and various saline substances, besides free malic acid and silica. Dr. Probst, of Heidelberg, has more recently found in it a peculiar acid denominated *cheledonic acid*; two alkaline principles, one of which forms neutral salts with the acids and is called *chelerythrin* in consequence of the intense redness of its salts, the other unites with but does not neutralize the acids, and is named *chelidomin*; and lastly a neuter, crystallizable, bitter principle, which from its yellow colour he calls *chilidoxanthin*. Of these principles, chelerythrin appears to rank among the acrid narcotic poisons. (*Annal. der Pharm.* xxix. 113.) The discovery of two alkaline principles in celandine is ascribed in the *Journal de Chim. Med.* to M. Polex. (See *Am. Journ. of Pharm.* xii. 328.) Celandine is an acrid purgative, possessed also of diuretic, and perhaps diaphoretic and expectorant properties. In over doses, it produces unpleasant effects, and is by some considered poisonous. By the ancients it was much esteemed as a remedy in jaundice; and it has been found useful in the same complaint by some modern physicians. It was the chief ingredient of the old *decoctum ad ictericos* of the Edinburgh Pharmacopœia. It has been given also, with asserted advantage, in various other complaints, especially those of a scrofulous character, affecting the mesenteric and lymphatic glands, the skin, and the eyes. The yellow juice is often applied, in domestic practice, to corns and warts, which it destroys by stimulating them beyond their vital powers. The dose of the dried root or herb is from thirty grains to a drachm, that of the fresh root one or two drachms; and the same quantity may be given in infusion. The watery extract and the expressed juice have also been employed. The dose of the former is from five to ten grains, that of the latter from ten to twenty drops. In each case, the dose is to be gradually increased, until the effects of the remedy are experienced.

CHELTENHAM SALT, ARTIFICIAL. Several artificial mixtures have been prepared, professing to be exact imitations of the saline ingredients in the chalybeate Cheltenham water; but the only one which appears worthy of confidence, is that prepared by Robert Alsop, Chemist, of London. The composition of the natural Cheltenham chalybeate is given at p. 113, under the head of *Aqua*. The imitation of Mr. Alsop, as analyzed by Mr. Faraday, contains the same solid and gaseous contents as the natural water, except the sulphate of lime, which is very properly omitted; and in the same proportions precisely, with the exception that there is about twice as much free carbonic acid in the artificial preparation. The iron is present in the state of protoxide, and is immediately dissolved by the free carbonic acid, upon adding a sufficient quantity of water to the mixed salts. The free carbonic acid probably exists as such in the dry mixture; as there is no obvious agent present to cause it to be disengaged in the mere act of solution.

This saline mixture is in the form of a white powder, possessing a saline and slightly ferruginous taste. It is put up in bottles of two sizes, the smaller containing two and a half ounces, or sufficient to make thirty doses of forty grains each. It forms a good combination, in which the aperient property of the salts present is combined with the tonic virtue of the iron. It is considered to be useful in glandular obstructions, especially of the liver, and in scrofulous affections, attended with feeble digestion, sluggish bowels, and pallidness of skin. It is employed also, with advantage, in sick headache, habitual costiveness, and hemorrhoids. The dose is a teaspoonful, quickly dissolved in half a pint of cold water, and swallowed immediately, before the iron has time to separate in an insoluble state. This quantity may be taken in the morning, fasting, and repeated once or twice after an interval of twenty minutes, or in the course of the day. To obtain its full tonic and alterative effects, it should be persevered in for a month or six weeks.

CHLORIDE OF POTASSA, SOLUTION OF. *Liquor Potassæ Chlorinatæ. Javelle's Water. Eau de Javelle.* This is obtained precisely as the solution of chlorinated soda. (See *Liquor Sodæ Chlorinatæ*.) It is employed for taking out fruit stains, &c., from linen. In chemical constitution it is probably a hypochlorite.

CHLORIDE OF SILVER. *Argenti Chloridum.* This has been already referred to as being inevitably formed when nitrate of silver is given internally. (See page

870.) It is readily prepared by adding a solution of common salt to one of nitrate of silver, as long as it produces a precipitate. As first thrown down it is a white curdy substance, but it soon becomes discoloured when exposed to the light. It has been used rubbed on the tongue in syphilis, and internally in epilepsy, chronic dysentery and diarrhoea, and other diseases in which nitrate of silver has been given. The dose is three grains or more four or five times a day. It is a compound of doubtful therapeutic value. The crystallized *ammonio-chloride of silver* has been given in syphilitic affections, in the dose of one fourteenth of a grain. It is formed by saturating solution of ammonia, by the assistance of heat, with chloride of silver, and allowing the liquid to cool in a stopped bottle. It crystallizes in cubes, and is very liable to decomposition.

CHLORINE ETHERS. There appear to be three species of chlorine ether, each consisting of some form of hydrocarbon, united with different proportions of chlorine. The first is called *protochlorine ether*, and is formed by passing an excess of chlorine through cold alcohol. It consists of one eq. of chlorine 35.42, and one of etherine 28.48. The second, denominated *bichlorine ether*, consists of two eqs. of chlorine and one of etherine, and is the long known oily liquid of the Dutch chemists, obtained by the action of olefiant gas on chlorine. The third species was discovered within a few years by three chemists, independently of each other—Soubeiran in France, Liebig in Germany, and Guthrie in this country. Dumas has determined its composition to be three eqs. of chlorine to one of bicarburet of hydrogen, and ascertained that it differs from formic acid, into which it is susceptible of conversion by the action of potassa, in containing an equivalent quantity of chlorine, in place of the oxygen of that acid. On account of its connexion with formic acid, it is called by the French chemists *chloroforme*, which may be rendered in English *chloroformid*. It is this latter compound which it is the object more particularly of this article to describe.

Chloroformid was obtained by Mr. Guthrie by distilling a gallon from a mixture of three pounds of chloride of lime and two gallons of alcohol of sp. gr. 0.844, and rectifying the product by redistillation, first from a great excess of chloride of lime, and afterwards from strong sulphuric acid. Thenard recommends it to be obtained by dissolving one part of chloride of lime in three parts of water, decanting the solution, adding from one-fifth to one-tenth of alcohol, and distilling from a retort sufficiently capacious to guard against the overflowing of the materials when they swell. In the receiver water will condense, swimming over an oleaginous liquid. The water is decanted, and the oily liquid, being agitated several times with concentrated sulphuric acid, and rectified from finely powdered baryta, will furnish pure *chloroformid*.

This compound is a colourless oleaginous liquid, of a sweetish ethereal odour, and hot, aromatic, peculiar taste. It boils at 142°, and has the sp. gr. of 1.480. It is not inflammable, but renders the flame of an alcohol lamp yellow and fuliginous. It is scarcely acted on by sulphuric acid in the cold, but dissolves readily in alcohol and ether, from its solution in which it is precipitated by water. The alcoholic solution forms, when sufficiently diluted with water, an aromatic and saccharine liquid of a very grateful taste.

Medical Properties. Mr. Guthrie was led to prepare this ether by his peculiar process from noting a passage in Professor Silliman's *Elements of Chemistry*, which referred to the chloric ether of the Dutch chemists as being a grateful diffusible stimulant, when properly diluted. He supposed that he had fallen upon a cheap and easy process for obtaining this long known ether, without being aware that in reality he had obtained a new compound of the same class. Specimens of it were transmitted to Professor Silliman, who distributed portions among his medical friends. It appears to act as a diffusible soothing stimulus, in the same manner as sulphuric ether, but with this decided advantage, that, when sufficiently diluted, it possesses a bland, sweet taste, which renders its administration easy, even to children. It has been used with advantage in asthma, spasmodic cough, the sorethroat of scarlet fever, atonic quinsy, and other diseases in which a grateful and composing medicine is indicated. Professor Ives, and Dr. N. B. Ives, of New Haven, speak favourably of its effects. The dose for an adult is a teaspoonful, diluted with water. In affections characterized by difficult respiration, it may be used by inhalation. It is employed for medicinal purposes in alcoholic solution.

CHROME YELLOW. This is the neutral chromate of lead, prepared by precipitating a solution of the nitrate of lead with chromate of potassa. It is of a beautiful lemon-yellow colour. The subchromate of lead, consisting of one eq. of acid, and two eqs. of base, is of a red colour, and is sometimes used as a pigment. *Chrome green* is a mixture of chrome yellow and Prussian blue.

CICHORIUM INTYBUS. *Succory.* A perennial herbaceous plant, indigenous in Europe, but naturalized in this country, where it grows in fields, and in roads along the fences, in neighbourhoods which have been long settled. It is one or two feet high, with large, compound, beautifully blue flowers, which appear in July and August, and serve to distinguish the plant at first sight. The whole plant has a bitter taste, without acrimony, or any very peculiar flavour. The taste is strongest in the root, and weakest in the flowers. The leaves, when young and tender, are said to be sometimes eaten as salad in Europe. Succory is gently tonic without being irritating, and is considered by some authors as aperient and deobstruent. It is said to be useful, if freely taken, in hepatic congestion, jaundice, and other visceral obstructions in the early stages; and it is affirmed to have done good even in pulmonary consumption. The usual form of administration is that of decoction, which is prepared by boiling one or two ounces of the root, or a handful of the herb, in a pint of water. The root dried and roasted has acquired some popularity in certain parts of Europe, as a substitute for coffee. The common *garden endive* is a species of *Cichorium*, denominated *C. Endivia*.

CICUTA VIROSA. *Water Hemlock. Cowbane.* A perennial, umbelliferous European plant, growing on the borders of pools and streams. It is exceedingly poisonous, proving fatal to most animals which feed upon it, though said to be eaten with impunity by goats and sheep. Several instances are on record of children who have died from eating the root by mistake for parsnip. It operates as an acrid narcotic, producing inflammation of the stomach, together with symptoms which indicate cerebral disturbance, such as vertigo, intoxication, and convulsions. When it vomits, as it frequently does, fatal effects are less apt to ensue. The plant is said to be less poisonous in the dried than the recent state; and it has been hence inferred that the active principle is volatile. But the volatile oil, obtained by distillation, was found by Simon, an apothecary of Berlin, not to be poisonous. On the other hand, the alcoholic extract of the dried root operated as a violent poison upon the animals to which it was given. (*Annal. der Pharm.* xxxi. 258.) It is at present never used internally as a medicine, having been superseded by the *Conium maculatum*, which is considered safer. Externally, it is sometimes applied as an anodyne poultice in local pains, particularly those of a rheumatic or gouty nature.

The *Cicuta maculata* or *American water hemlock* is closely analogous, in botanical character, and in its operation upon the system, with the European species. In several instances, children have been fatally poisoned by eating its root. It is never used in medicine. For a full account of this plant, the reader is referred to Bigelow's Medical Botany, vol. i. page 125. In cases of poisoning by either of these plants, vomiting should be induced as speedily as possible, and maintained till the stomach is thoroughly evacuated.

CITRATE OF AMMONIA. *Ammonia Citras.* This is employed in the liquid form. The solution is made by saturating lemon or lime-juice, or an equivalent solution of citric acid (see page 429), with carbonate of ammonia, and may be given in the dose of a tablespoonful. A more elegant mode of exhibition is that of an extemporaneous effervescing draught. To half a fluidounce of lemon-juice mixed with an equal quantity of water, or to a fluidounce of a solution of citric acid containing seventeen grains of the acid, is to be added half a fluidounce of a solution containing thirteen grains of the carbonate (sesquicarbonate) of ammonia; and the mixture is to be given while effervescing. The dose, in either case, may be repeated every hour, two, or three hours. The preparation is given as a refrigerent diaphoretic in febrile complaints, and is especially applicable to typhoid fevers with a hot, dry skin.

CITRATE OF IRON. *Ferri Citras.* The citrates of iron were first introduced to the notice of the medical profession, in 1831, by M. Beral, of Paris. The *citrate of the protoxide* is prepared by digesting iron filings in an aqueous solution of citric acid. It is a white, pulverulent, slightly soluble salt, having a strongly chalybeate taste, and absorbing oxygen readily when exposed to the air. The *citrate of the sesquioxide* is the salt usually recommended for medical use. It is made by saturating a boiling solution of crystallized citric acid in an equal weight of water, with moist hydrated sesquioxide of iron. The solution, when cold, is filtered, and diluted so as to be equal to four times the weight of the acid employed. It is then spread out on a surface of glass, where it speedily dries in thin layers, which are separated, and broken into fragments. As thus obtained, it is in thin pieces, of a brilliant golden red colour. It is an uncrystallizable acid salt, slowly soluble in cold water, readily soluble in boiling water, and having an acid, not unpleasant taste. When the excess of acid is neutralized by adding ammonia to its solution, the double

salt is formed, called *ammonio-citrate of iron*. This is in yellowish-green, soft, porous masses, having an acidulous, slightly chalybeate taste. It is much more readily soluble in water than the citrate of the sesquioxide. The *citrate of the black or magnetic oxide* is an uncrystallizable greenish-yellow salt, susceptible of being formed into transparent laminae, very soluble in water, unalterable in solution, even when exposed to the air, and having a decidedly chalybeate taste. These different citrates have latterly been used as pleasant chalybeates. The dose is five grains or more, repeated several times a day. The citrate of the sesquioxide is best given in pill; the ammonio-citrate and the citrate of the black oxide, in solution. The citrate of the sesquioxide may be readily rendered soluble in water, by the addition of a few drops of the officinal liquor ammoniæ.

CIVET. *Zibethum*. This is an odorous substance, obtained from two animals of the genus *Viverra*, viz., the *V. Civetta* or civet-cat of Africa, and the *V. Zibetha* which inhabits the East Indies. It is secreted into a cavity which opens between the anus and external genitals, and is collected from animals confined for the purpose. It is semi-liquid, unctuous, yellowish, becoming brown and thicker by exposure to the air, of a very strong, peculiar odour, similar to that of musk, though less agreeable and less diffusible, and of a bitterish, subacid, disagreeable, fatty taste. When heated it becomes quite fluid, and at a higher temperature takes fire, and burns with a clear flame, leaving little residue. It is insoluble in water, and only slightly soluble in ether and cold alcohol; but heated alcohol dissolves it almost entirely, depositing it again upon cooling. It contains, among other ingredients, a volatile oil, fat, and free ammonia. In medicine it was formerly employed as a stimulant and antispasmodic, like castor and musk; but it is now used exclusively as a perfume.

CLEMATIS ERECTA. *Upright Virgin's Bower*. A perennial plant growing wild on the continent of Europe. The leaves and flowers have an acrid burning taste, and if long retained in the mouth produce blisters. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing; and applied to the skin they produce inflammation and vesication. Hence the name of *flammula Jovis*, by which the plant was known in older pharmacy. The acrimony is greatly diminished by drying. Störck found this species of Clematis very useful in secondary syphilis, cancerous and other foul ulcers, and severe headaches. He gave it internally, and at the same time applied the powdered leaves to the surface of the sore. It acted as a diuretic and diaphoretic. Two or three drachms of the leaves were infused in a pint of water, of which he administered four ounces three times a day. He also employed an extract, in the dose of a grain or two in the course of a day; but this preparation must have been nearly inert. At present the plant is not used.

Other species of Clematis have the same acrid properties. Among these are the *C. Flammula*, or *sweet-scented virgin's bower*, which, though a native of Europe, is cultivated in our gardens, the *C. Vitalba* or *traveller's joy*, also a native of Europe, and several indigenous species, of which the *C. Virginica* or *common virgin's bower*, the *C. Viorna* or *leather flower*, and the *C. crispa* have been particularly cited by authors as proper substitutes for the *C. erecta* used by Störck. All these are climbing plants. The *C. Vitalba* has been used in Europe with success in the cure of itch. For this purpose the roots and stems, bruised, and boiled for a short time to diminish their acrimony, were infused in boiling oil, which, thus impregnated, was applied to the skin several times a day. Twelve or fifteen applications were usually sufficient to effect a cure.

COBALT BLUE. This beautiful pigment is a compound of oxide of cobalt and alumina, obtained by precipitating the mixed solutions of a salt of alumina and of cobalt by means of an alkali, and washing, drying, and strongly calcining the precipitate. (*Berzelius*.) The cobalt blue of Thenard is made by heating together the hydrated subphosphate of cobalt and hydrate of alumina. It is used in painting.

COBWEB. *Spider's Web*. *Tela Araneæ*. The genus *Aranea* of Linn. has been divided by subsequent naturalists into several genera, of which the *Tegeneria* of Walkenaer is the one that includes the medicinal species of spider. The *T. domestica* of Europe, and *T. medicinalis* of this country (Henz, *Journ. Acad. of Nat. Scien.* ii. 53), are the particular species which have attracted most attention. They inhabit cellars, barns, and other dark places, and are of a brown or blackish colour. It is affirmed that the web of the field spider is inefficacious, while that collected in the cellars of houses, &c., has extraordinary medical virtues. Several authors speak in very decided terms of its powers as a febrifuge and antispasmodic. According to Dr. Robert Jackson, it is superior even to bark and arsenic in the cure of intermittents, and is,

moreover, highly useful in various spasmodic and nervous diseases, controlling and tranquillizing irregular nervous action, exhilarating the spirits, and disposing to sleep, without producing any of the narcotic effects of opium on the brain. These praises are to a certain extent echoed by Dr. Chapman and Dr. Eberle, in their respective works on Therapeutics and Materia Medica. Among the complaints in which it has been found useful, besides intermittent fever, are periodical headache, the hectic fever of consumption, asthma, hysteria, and nervous irritations attended with morbid vigilance and irregular muscular action. It will be observed that these are, for the most part, affections over which the imagination has much control. The dose of spider's web is five or six grains, to be given in the form of pill, and repeated every three or four hours. Dr. Jackson states that its influence is not in proportion to the quantity administered, and that he obtained the same effects from ten as from twenty grains. This might well be, if the supposition be allowed, that its chief operation is through the mind of the patient. Spider's web has also been used externally, with asserted advantage, as a styptic in wounds, and a healing application in superficial ulcers. Spiders themselves were formerly employed in the treatment of intermittent fever, and the application of the web to the cure of this disease is not a measure of recent origin.

COCOA. *Cacao. Chocolate Nuts.* These are the seeds of the *Theobroma Cacao*, a handsome tree, from twelve to twenty feet in height, growing in Mexico, the West Indies and South America, in some parts of which it is largely cultivated, particularly in Guayaquil and Venezuela. The fruit is an oblong ovate capsule or berry, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell, and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the *cocoa* of commerce. They have a slightly aromatic, bitterish, oily taste, and, when bruised or heated, an agreeable odour. They contain a large quantity of fixed oil, together with albumen and bitter extractive. The oil is obtained by hot expression, or by decoction. It is a soft solid, whitish or yellowish, with a peculiar agreeable odour, and a bland pleasant taste, and is known by the name of *cocoa butter*. According to Brandes, it has peculiar properties, and yields a peculiar acid when saponified. He calls the oil *cocin*, and the acid *cocinic acid*. (*Journ. de Pharm.* xxiv. 652.) The oil is said to be frequently adulterated with animal fats. The chief use to which it is applied, is as an ingredient in cosmetic unguents. A peculiar crystallizable azotized principle, called *theobromine*, has been found in the seeds by M. Wokresensky. It is said to contain a larger proportion of nitrogen than caffeine. (*Journ. de Pharm.* N. S. i. 136.) The shells of the nuts are sometimes employed in the state of infusion, as a substitute for tea or coffee. They impart to boiling water a taste analogous to that of chocolate, but weaker. The kernel is consumed in great quantities, in the shape of chocolate, or in some analogous form.

Chocolate is differently prepared in different countries. In Great Britain and the United States, it usually consists, when pure, exclusively of the cocoa nuts, which are first roasted, then deprived of their shell, and lastly reduced, by grinding between heated stones, to the state of a paste, which is moulded into oblong cakes. Not unfrequently rice flour or other farinaceous substance, with butter or lard, is added; but these must be considered as adulterations. On the continent of Europe, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added. Vanilla is a favourite addition in South America, France, and Spain. Cocoa is often sold in the state of powder, which is sometimes mingled with other ingredients, such as ground rice, barley flour, sugar, &c. Chocolate is prepared for use by reducing it to powder, and boiling it in milk, water, or a mixture of these fluids. In this state it is much employed as a drink at the morning and evening meals, and serves as an excellent substitute for coffee in dyspeptic cases, being nutritive and digestible, without exercising any narcotic or otherwise injurious influence. It is also a good article of diet for convalescents, and may sometimes be given advantageously as a mild nutritive drink in cases of disease, though, under these circumstances, it should usually be prepared without milk, and of less strength than as ordinarily used.

COD-LIVER OIL. *Oleum Jecoris Aselli. Huile de Morue, Fr.* A fixed oil obtained from the livers of codfish, *Gadus Morrhua* of naturalists, and from those of other allied species. It is procured by exposing the livers, in tubs or vats, to the sun's rays. The oil flows out spontaneously, and is collected in proper vessels. That which first flows is limpid and of a light-yellowish colour. After the commencement of putrefac-

tion, a darker coloured, and offensive oil flows out, which is unfit for medical use. The oil is also separated by expression, and by means of heat; and in both ways, if the livers be quite fresh, and proper care be taken, it may be procured of good quality. Mr. Donovan recommends the following mode of preparation. The livers, perfectly sound and fresh, are to be placed in a clean iron pot over a slow fire, and stirred until they assume the condition of a pulp, care being taken that the mass be not heated beyond 192°. When this temperature is attained, the pot is to be removed from the fire, and its contents introduced into a canvass bag, through which water and oil will flow into a vessel beneath. After twenty-four hours, the oil is to be decanted and filtered through paper. In this state it is pale yellow, with little odour, and a bland not disagreeable taste. As ordinarily found in the market, and employed for manufacturing purposes, the oil is brown, very offensive, and scarcely fit for internal use. On the continent of Europe, three, and according to some, four varieties are distinguished, viz. the white, the yellow, the red, and the brown. It is possible that the colour may sometimes depend upon the species of fish from which the oil is procured; but more commonly the difference arises from the degree of care used in the preparation. If the livers be putrid, or be exposed to too great a heat, or too strongly expressed, or if they be originally diseased or of bad quality, the oil is more or less inferior. That should be selected for medical use which is least offensive to the palate and nostrils.

Cod-liver oil has been found to contain variable proportions of iodine and bromine. The former was detected by L. Gmelin (*Annal. der Pharm.* xxx. 321); and both by Herberger (*Pharm. Central-Blatt*, 1837, s. 536). It has long been popularly used in various diseases, but has only within a few years attracted the general notice of the profession. It has been much lauded on the continent of Europe, particularly in Germany and Switzerland, as a remedy in chronic gouty and rheumatic affections, scrofula and rickets, chronic pectoral complaints, tabes mesenterica, obstinate constipation, incontinence of urine, and intestinal worms. The dose is a tablespoonful three or four times a day for adults, a teaspoonful repeated as frequently for children, which may be gradually increased as the stomach will permit, and continued for a long time. It may be taken alone, or mixed with some mucilaginous liquid. It is sometimes applied externally by friction, and, in cases of ascarides or lumbricoides, is injected into the rectum. It has been recommended also as a local application in paralysis, various chronic cutaneous eruptions, and opacity of the cornea, after the subsidence of inflammation. In the last mentioned affection, one or two drops of the oil are applied by means of a pencil to the cornea, and diluted, if found too stimulating, with olive or almond oil.

COFFEE. The coffee plant—*Coffea Arabica*—belongs to the class and order Pentandria Monogynia of the sexual system, and to the natural order Cinchonaceæ of Lindley. It is a small tree, rising from fifteen to twenty feet in height, and in favourable situations sometimes even thirty feet. The branches are opposite, the lower spreading, the upper somewhat declining, and gradually diminishing in length as they ascend, so as to form a pyramidal summit, which is covered with green foliage throughout the year. The leaves are opposite, upon short footstalks, oblong-ovate, acuminate, entire, wavy, four or five inches long, smooth and shining, of a dark green colour on their upper surface, paler beneath, and accompanied with a pair of small, pointed stipules. The flowers are white, with an odour not unlike that of the jasmine, and stand in groups in the axils of the upper leaves. The calyx is very small, the corolla salverform, with a nearly cylindrical tube, and a flat border divided into five lanceolate, pointed segments. The stamens project above the tube. The fruit, which is inferior, is a roundish berry, umbilicate at top, at first green, then red, and ultimately of a dark purple colour. It is about as large as a cherry, and contains two seeds, surrounded by a paper-like membrane, and enclosed in a yellowish pulpy matter. These seeds, divested of their coverings, constitute coffee.

This tree is a native of Southern Arabia and Abyssinia, and probably pervades Africa about the same parallel of latitude, as it is found growing wild at Liberia on the western coast of the continent. The value of its produce has led to its extensive cultivation in various parts of the world where the temperature is sufficiently elevated and uniform. Considerable attention has long been paid to its culture in its native country, particularly in Yemen, in the vicinity of Mocha, from which the demands of commerce were at first almost exclusively supplied. About the year 1690, it was introduced by the Dutch into Java, and in 1718 into their colony of Surinam. Soon after this latter period, the French succeeded in introducing it into their West India islands, Cayenne, and the Isles of France and Bourbon: and it has subsequently made

its way into the other West India Islands, various parts of tropical America, the peninsula of Hindostan, and Ceylon.

The tree is raised from the seeds, which are sown in a soil properly prepared, and germinating in less than a month, produce plants which at the end of the year are large enough to be transplanted. These are then set out in rows at suitable distances, and in three or four years begin to bear fruit. It is customary to top the trees at this age, in order to prevent their attaining an inconvenient height, and to increase the number of fruit-bearing branches. It is said that they continue productive for thirty or forty years. Though almost always covered with flowers and fruit, they yield most abundantly at two seasons, and thus afford two harvests during the year. Various methods are employed for freeing the seeds from their external coverings; but that considered the best, is by means of machinery to remove the fleshy portion of the fruit, leaving the seeds surrounded only by their papyraceous envelope, from which they are afterwards separated by drying, and by the action of peeling and winnowing mills.

The character of coffee varies considerably with the climate and mode of culture. Consequently several varieties exist in commerce, named usually from the sources from which they are derived. The *Mocha coffee*, which is in small and roundish grains, takes precedence of all others; but very little of it is now imported into Europe or America. The *Java coffee* is generally esteemed most highly in this country, and commands the highest price; but our chief supplies are derived from the West Indies and South America. Some good coffee has been brought from Liberia. Coffee is thought to improve by age, losing a portion of its strength, and thus acquiring a more agreeable flavour. It is said to be much better when allowed to become perfectly ripe upon the tree, than as ordinarily collected. The grains should be hard, and so heavy as readily to sink in water. When soft, light, black or dark coloured, or musty, they are inferior.

The general aspect of coffee is too well known to need description. It has a faint peculiar odour, and a slightly sweetish, somewhat austere taste, entirely different from that developed by roasting. From the experiments of Seguin, Schrader, Robiquet and Pelletier, and other chemists, it appears to contain a minute quantity of volatile oil, a fixed oil, gum, resin, an extractive matter having the characteristic taste of the coffee and affording a dark green precipitate with the salts of iron, albumen, a little sugar, saline substances, lignin, and a peculiar crystallizable principle which has received the name of *cafein*. This was first discovered by Runge, and afterwards by Robiquet. It may be obtained in the following manner. Exhaust bruised coffee by two successive portions of boiling water, unite the infusions, add acetate of lead in order to precipitate the principles which accompany the *cafein*, filter, decompose the excess of acetate of lead in the filtered liquor by sulphuretted hydrogen, and evaporate to the point of crystallization. The crystals which form may be purified by again dissolving them in water and evaporating. This is the process employed by Runge. (*Berzelius, Traité de Chim.*) Pelletier obtained *cafein* by submitting the alcoholic extract of coffee to the action of water, treating the solution thus obtained with magnesia, filtering, evaporating the filtered liquor to the consistence of syrup, treating the residue with alcohol, and filtering and evaporating the alcoholic solution. (*Dict. des Drogues.*) *Cafein* crystallizes, by the cooling of its concentrated solution, in opaque, silky, flexible needles; by slow and spontaneous evaporation, in long, transparent prisms. It has a feebly bitter and disagreeable taste, is soluble in water and alcohol, but insoluble in ether and oil of turpentine, has neither an acid nor alkaline reaction, melts when exposed to heat, and at a higher temperature sublimes, without residue, into needles analogous to those formed by benzoic acid. It is remarkable for containing a larger proportion of nitrogen than almost any other proximate vegetable principle, and in this respect equals some of the most highly animalized products. The present views of its composition are represented by the formula $C H N_2 O_2$; and it is believed to be identical with thein, or the peculiar principle of tea. (*Turner's Chemistry, 7th Lond. Ed.*) Notwithstanding the quantity of nitrogen in its composition, *cafein* does not putrefy, even when its solution is kept for some time in a warm place. In addition to the facts above stated in relation to the composition of coffee, Pfaff ascertained that, in the precipitate produced by acetate of lead with the decoction, there are two peculiar principles, one resembling tannin, the other having acid properties, and called by him *cafeic acid*.

Coffee undergoes considerable change during the roasting process. It swells up very much, acquiring almost double its original volume, while it loses about 20 per cent. of its weight. It acquires, at the same time, a peculiar odour entirely different from that of the unaltered grains, and a decidedly bitter taste. A volatile oil is de-

veloped during the process, and, according to Chenevix, a portion of tannin. The *cafein* does not appear to undergo material change, as, according to Garot, it may be extracted unaltered from the roasted coffee. The excellence of the flavour of roasted coffee depends much upon the manner in which the process is conducted, and the extent to which it is carried. It should be performed in a covered vessel, over a moderate fire, and the grains should be kept in constant motion. When these have acquired a chestnut-brown colour, the process should cease. If too long continued, it renders the coffee unpleasantly bitter and acrid, or by reducing it to charcoal, deprives it entirely of flavour. The coffee should not be burnt long before it is used, and should never be kept in the ground state, as it loses much of its agreeable flavour and activity.

Medical and Economical Uses.—More attention has been paid to the effects of coffee on the system in the roasted than in the crude state. Unroasted coffee has been employed by Dr. Grindel of Russia in intermittent fevers, and the practice has been followed by some other physicians; but the success, though considerable, was not such as to lead to the conclusion that this medicine would answer as a substitute for Peruvian bark. It was given in powder in the dose of a scruple every hour, or in decoction prepared by boiling an ounce with eighteen ounces of water down to six, or in the state of extract in the dose of from four to eight grains. Whether its operation corresponds with that of the roasted coffee we are unable to say. The following observations relate only to the latter.

The action of coffee is directed chiefly to the nervous system. When swallowed it produces a warming cordial impression on the stomach, quickly followed by a diffused agreeable nervous excitement, which extends itself to the cerebral functions, giving rise to increased vigour of imagination and intellect, without any subsequent confusion or stupor such as characterizes the action of narcotic medicines. Indeed one of its most extraordinary effects is a disposition to wakefulness, which continues for several hours after it has been taken. It is even capable of resisting, to a certain extent, the intoxicating and soporific influence of alcohol and opium, and may sometimes be advantageously employed for this purpose. It also moderately excites the circulatory system, and stimulates the digestive function. A cup of coffee taken after a hearty meal, will often relieve the sense of oppression so apt to be experienced, and enable the stomach to perform its office with comparative facility. These exhilarating effects of coffee, united with its delicious flavour when suitably qualified by cream and sugar, have given rise to its habitual employment as an article of diet. Its use for this purpose has prevailed from time immemorial in Persia and Arabia. In 1517 it was introduced by the Turks into Constantinople, whence it was carried to France and England about the middle of the succeeding century, and has since gradually made its way into almost universal use. It cannot be supposed that a substance capable of acting so energetically upon the system, should be entirely destitute of deleterious properties. Accordingly, if taken in very large quantities, it leaves, after its first effects are passed, a degree of nervous derangement or depression equivalent to the previous excitement; and its habitual immoderate employment is well known very greatly to injure the tone of the stomach, and frequently to give rise to troublesome dyspeptic and nervous affections. This result is peculiarly apt to take place in individuals of naturally susceptible nervous systems, and in those of sedentary habits. We have repeatedly known patients who have long suffered with headache and vertigo, to get rid of these affections by abstaining from coffee.

In the treatment of disease, coffee has been less employed than might have been expected from its effects upon the system. There can be no doubt that it may be advantageously used in various nervous disorders. In a tendency to stupor or lethargy dependent on deficient energy of the brain, without congestion or inflammation, it would be found useful by stimulating the cerebral functions. In light nervous headaches, and even in sick headache not caused by the presence of offending matter in the stomach, it often proves temporarily useful. It has acquired much reputation as a palliative in the paroxysm of spasmodic asthma, and is recommended by some writers in hysterical affections. The Egyptians are said to have formerly employed it as a remedy in amenorrhœa. Hayne informs us that in a case of violent spasmodic disease, attended with short breath, palpitation of the heart, and a pulse so much increased in frequency that it could scarcely be counted, immediate relief was obtained from a cup of coffee, after the most powerful antispasmodics had been used in vain for several hours. It is said also to have been used very effectually in obstinate chronic diarrhœa; and Dr. Chapman, of Philadelphia, has found it highly useful in calculous nephritis. In all inflammatory affections of a high grade it is contra-indicated.

Coffee is usually prepared in this country by boiling the roasted grains, previously ground into a coarse powder, in water for a short time, and then clarifying by the white of an egg. Some prefer the infusion, made by a process similar to that of displacement. It has more of the aroma of the coffee than the decoction, with less of its bitterness. It is usually made by a process similar to that of displacement. The proper proportion for forming the infusion for medical use is an ounce to a pint of boiling water, of which a cupful may be given warm for a dose, and repeated if necessary.

COLLINSONIA CANADENSIS. *Horse-weed. Horse-balm. Richweed. Heal-all. Stone-root. Knot-root.* An indigenous plant, with a perennial, knotty root, and an herbaceous simple stem about two feet high, furnished with two or three pairs of broad, cordate ovate, smooth leaves, and terminating in a panicle of yellow flowers in branched racemes. The flowers are diandrous and monogynous, with a labiate calyx and corolla, the latter of which has the lower lip fringed. The plant grows in woods from Canada to Carolina, and flowers from July to September. The whole plant has a strong disagreeable odour, and a warm pungent taste. It is considered tonic, astringent, diaphoretic, and diuretic; and the root in substance is said to irritate the stomach and produce vomiting even in small doses. The plant is used in numerous complaints in domestic practice. It is preferred in the fresh state, as the active principle is volatile. A decoction of the fresh root is said to have been used with advantage in catarrh of the bladder, leucorrhœa, gravel, dropsy, and other complaints; and the leaves are applied by the country people, in the form of cataplasm or fomentation, to wounds, bruises, and sores, and in cases of internal abdominal pains.

COLUTEA ARBORESCENS. *Bladder Senna.* A shrub, growing spontaneously in the southern and eastern parts of Europe, and cultivated in gardens as an ornamental plant. Its leaves are pinnate, consisting of from three to five pairs of leaflets, with an odd one at the end. The leaflets are obovate, slightly emarginate, smooth and of a deep-green colour on the upper surface, grayish-green and somewhat pubescent beneath. The flowers are yellow, and the fruit vesicular, whence the plant derived its vulgar name. The leaflets are possessed of purgative properties, and, in some parts of Europe, are used as a substitute for senna, which is said to be sometimes adulterated with them. The bladder senna is comparatively very feeble. It is administered in infusion or decoction, of which the dose is about half a pint, containing the virtues of from one to three ounces of the leaves.

COMPTONIA ASPLENIFOLIA. *Sweet Fern.* A shrubby indigenous plant, named from the resemblance of its leaves to the *spleenwort fern*, but belonging to the Linnean class and order *Monœcia Triandra*. It grows in thin sandy or stony woods, from New England to Virginia. All parts of it possess a resinous spicy odour, which is increased when the plant is rubbed. It is said to be tonic and astringent, and to be occasionally used in domestic practice as a remedy in diarrhœa, and various other complaints. It is employed in the form of decoction.

CONVALLARIA MAJALIS. *Lily of the Valley.* This charming little garden flower is a native of Europe, and is found growing wild in the United States, upon the highest mountains of Virginia and Carolina. The flowers have a strong delightful odour, which is in great measure lost by drying. Their taste is nauseous, bitter, and acrid. Taken internally they are said to be emetic and cathartic, and their extract purges actively in the dose of half a drachm. They were formerly used in epilepsy and against worms. At present they are employed only as a sternutatory, for which purpose they are dried and reduced to a coarse powder. The root, which is also bitter, has similar purgative properties, and, reduced to powder, is said to be sternutatory.

CONVALLARIA POLYGONATUM, Linn. *Polygonatum uniflorum,* Desfontaines. *Solomon's seal.* A perennial, herbaceous, European plant, the root of which is horizontal, jointed, white, and marked, at short intervals, with small circular impressions, which bear a remote resemblance to those made by a seal, and have served to give a name to the plant. The root is inodorous, and of a sweetish mucilaginous taste, followed by a slight degree of bitterness and acrimony. It is said to be emetic. In former times it was used externally in bruises, especially those about the eyes, in tumours, wounds, and cutaneous eruptions, and was highly esteemed as a cosmetic. At present it is not employed, though recommended by Hermann as a good remedy in gout and rheumatism. The berries and flowers are said to be acrid and poisonous.

The *C. multiflora* (*Polygonatum multiflorum*, Desf.), which grows in this country, as well as in Europe, is analogous to the preceding in properties.

COPAL. A resinous substance, brought from the East Indies, South America, and the western coast of Africa, but most abundantly from the first-mentioned source. It is the concrete juice of different trees, and is furnished by exudation. The East India copal has been supposed to be derived from the *Vateria Indica* of Linn, the *Eleo-carpus copalliferus* of Retzius; and the Brazilian is attributed by Martius and Hayne, probably with justice, to different species of *Hymenæa*. There is some reason to believe that the E. India copal is also the product of a species of *Hymenæa*; at least a specimen of this resin was collected by M. Perottet from the *Hymenæa Verrucosa*, which he found growing in the Isle of Bourbon. This tree is a native of Madagascar, and probably of the neighbouring parts of Africa; and M. Perottet was informed that the copal of India is taken thither by the Arabs of Muscat, who obtain it from the East coast of Africa. (*Journ. de Pharm.* 3ème série, i. 406.) Copal varies somewhat in appearance and properties, as procured from different sources. It is in roundish, irregular, or flatish pieces, colourless, yellowish, or brownish-yellow, more or less transparent, very hard, with a shining conchoidal fracture, inodorous and tasteless, of a sp. gr. varying from 1.045 to 1.139, insoluble in alcohol, soluble in ether, and slightly so in oil of turpentine. Some varieties unite with alcohol if suspended in its vapour while boiling. By heat it melts and is partially decomposed, becoming thereby soluble in alcohol and oil of turpentine. It is not a proximate principle, but consists of various resins united in different proportions. The East India copal is in flatter pieces than the American or African, and is whiter, softer, and less transparent. Two kinds are known in the drug market—the *crude* and the *scraped*—the former of a dull opaque appearance externally, the latter much clearer and more transparent, in consequence of being deprived of its outer coat. The process of *scraping* is said to consist in the removal of the exterior portion by means of an alkaline solution, which readily dissolves copal. This resin is used chiefly in the preparation of varnishes.

CORAL. A substance found at the bottom of the Mediterranean and other seas, supposed originally to belong to the precious stones, afterwards considered as a plant, but now universally admitted to belong to the animal kingdom. The *red coral* (*Corallium rubrum* of Lamarck, *Isis nobilis* of Linn.) is in the form of a small shrub, a foot or two in height, with a stem sometimes an inch or two in thickness, fixed to the rock by an expansion of the base, divided above into branches, and covered with a pulpy membrane, which is properly the living part, and which is removed when the coral is collected. The central portion is extremely hard, of various shades of red, susceptible of a brilliant polish, longitudinally striated, and formed of concentric layers, which are rendered obvious by calcination. Its chief constituent is carbonate of lime, which is coloured by oxide of iron, and united, as in similar calcareous products, with more or less animal matter. It was formerly very highly valued as a remedy in numerous diseases, but is in no respect superior to prepared oyster-shell, or other form of carbonate of lime derived from the animal kingdom. It was employed in the form of fine powder, or in different preparations, such as troches, syrups, conserves, tinctures, &c. At present it is valued chiefly as an ornament.

CORTEX CARYOPHYLLATA. *Cassia Caryophyllata.* *Clove Bark.* These names have been given to a bark, brought from the West Indies, and derived from a tree belonging to the family of the Myrtaceæ, supposed to be the *Myrtus acris* of Schwartz. It is usually in cylinders from one to two feet long by an inch in diameter, composed of numerous separate pieces rolled around one another, having a dark brown colour, a pungent taste, and an odour similar to that of cloves. It is sometimes in fragments, of a similar colour, taste, and smell, but softer and lighter, and supposed to be derived from older branches. A similar bark is said to be derived from the *Myrtus caryophyllata* of Linn., which grows in Ceylon. The clove bark has aromatic properties not unlike those of the spice from which it derived its name: but it is much inferior, and is now never used in this country. Some authors have confounded with it a wholly different bark produced by a tree growing in the Moluccas, and known by the Indian name of *culilawan*. (See *Culilawan*.)

CORYLUS ROSTRATA. *Beaked Hazel.* This is a small indigenous shrub growing especially in mountainous districts. The nut is invested with a scaly involucre, projecting beyond it like a beak, and thickly covered with short spiculæ like those of the *Mucuna pruriens*. These spiculæ have been employed by Dr. Heubener of Bethlehem, Pennsylvania, as an anthelmintic, and found to be efficacious. They operate in the same way as cowhage, and may be administered in the same manner and dose. See a communication from Mr. Duhamel in the *Am. Journ. of Pharm.* xiv. 280.

CRAB'S CLAWS. *Chelæ Cancrorum.* These, in a prepared state, were formerly

included in the Edinburgh Pharmacopœia, but were very properly omitted upon the recent revision of that work. Supposing them identical with the crust of the lobster, they consist, in the 100 parts, of 60 parts of carbonate of lime, 14 of phosphate of lime, and 26 of animal matter. They are prepared by levigation and elutriation, so as to bring them to a fine powder. They were formerly used as an absorbent and antacid; but the animal matter in their composition confers on them no peculiar virtues. They are given in the same dose with prepared chalk, over which they possess no superiority.

CRAB STONES. *Lapilli Cancrorum. Crabs' Eyes.* These are concretions, found in the stomach, one on each side, of the European crawfish, at the time the animal is about to change its shell. They are most abundantly procured in the province of Astracan in Asiatic Russia. The crawfish are bruised with wooden mallets, and laid up in heaps to putrefy. The animal remains are then washed away, and the stones picked out. They are inodorous, insipid bodies, somewhat hemispherical in shape, of a white or reddish colour, hard and stony consistence, and laminated texture. They are very variable in size, weighing from one to twelve grains each. They effervesce with acids, and, without dissolving, become converted, owing to the animal matter which they contain, into a soft transparent mass, retaining the original shape of the stone. By this character they are distinguished from counterfeit stones, which are sometimes fabricated of chalk, mixed with mucilaginous substances. They consist of carbonate and phosphate of lime, cemented together by animal matter. Crab stones have been used as an absorbent and antacid, and given in the same dose with prepared chalk. They were prepared for exhibition by being levigated in the usual manner. But they are now nearly obsolete, and are no longer official, having been expunged from the Edinburgh Pharmacopœia.

CUCURBITA CITRULLUS. *Watermelon.* The seeds of the watermelon are employed, to a considerable extent, as a domestic remedy in strangury and other affections of the urinary passages. They have the same properties with the seeds of the other Cucurbitaceæ, of which four different kinds were formerly official under the name of the *greater cold seeds*—viz. those of the *Cucurbita Pepo* or pumpkin, the *Cucurbita Lagenaria* or gourd, the *Cucumis Melo* or muskmelon, and the *Cucumis sativus* or cucumber. These, when bruised and rubbed up with water, form an emulsion which was formerly thought to possess considerable virtues, and was much used in catarrhal affections, disorders of the bowels and urinary passages, fever, &c. Of late, however, they have been entirely neglected, having been superseded by other more agreeable demulcents. The watermelon seeds are esteemed by some diuretic, as well as demulcent. They are usually given in the form of infusion, made in the proportion of one or two ounces of the bruised seeds to a pint of water, and taken *ad libitum*.

CULILAWAN. *Cortex Culilaban.* An aromatic bark, produced by the *Cinnamomum Culilawan* (*Laurus Culilawan*, Linn.), a tree of considerable size, growing in the Molucca islands, Cochinchina, and other parts of the East. It is usually in flat or slightly rolled pieces, several inches long, an inch or more in breadth, and one or two lines thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The epidermis is for the most part removed, but when present is of a light brownish-gray colour, soft to the touch, and somewhat spongy. The colour of the bark itself is a dull dark cinnamon-brown, the odour highly fragrant, the taste agreeably aromatic, and not unlike that of cloves. The active constituent is a volatile oil which may be separated by distillation. Culilawan has the medical properties common to the aromatics, but is scarcely used at present.

CUNILA MARIANA. *American Dittany.* A small indigenous perennial herb, growing on dry, shady hills, from New England to Georgia, and flowering in June and July. The whole herb has a warm pungent taste, and a fragrant odour, dependent on an essential oil which may be obtained separate by distillation with water. The medical properties of the plant are those of a gently stimulant aromatic, analogous to the mints, pennyroyal, &c. In the shape of warm infusion, it is popularly employed to excite perspiration in cold and slight fevers, to promote suppressed menstruation, to relieve flatulent colic, and for various other purposes to which the aromatic herbs are thought applicable.

CUTTLE-FISH BONE. *Os Sepiæ.* This is a calcareous body, situated underneath the skin, in the back of the *Sepia officinalis*, or *cuttle-fish*, which inhabits the seas of Europe, especially the Mediterranean, in the waters of which the bone is not unfrequently found floating. It is oblong-oval, from five to ten inches long, and from one and a half to three inches broad, somewhat convex on both sides, with thin edges,

of a rather firm consistence upon the upper surface, very friable beneath, and composed of numerous layers, loosely connected, so as to give to the mass a porous consistence. It is lighter than water, of a white colour, a feeble odour of sea-plants, and a saline taste. It contains, according to John, from 80 to 85 per cent. of carbonate of lime, besides animal matter, a little common salt, and traces of magnesia. Reduced by levigation and elutriation to a fine powder, it may be given as an antacid under similar circumstances with chalk or oyster-shell. It is sometimes used as an ingredient of tooth-powders. Small pieces of it are often put into bird-cages, that the birds may rub their bills against them; and the powder is employed for polishing. Another product of the cuttle-fish is a blackish-brown liquor, secreted by a small gland into an oval pouch, communicating externally near the rectum by a long excretory duct, through which the animal is said to have the power of ejecting it at will. This, when taken from the fish, is dried, and used in the preparation of the water colour called *sepia*.

CYANURET OF ZINC. *Zinci Cyanuretum*. This cyanuret is precipitated as a white insoluble powder, by adding cautiously, until it ceases to produce a precipitate, a recently filtered solution of cyanuret of potassium, obtained from the impure black cyanuret, to a solution of sulphate of zinc. It is used in Germany as a substitute for hydrocyanic acid, and is said to possess anthelmintic properties. It has been employed in epilepsy, chorea, and neuralgia, in several painful affections of the stomach, and in the colics attendant on difficult menstruation. The dose is a quarter of a grain, gradually increased to a grain and a half, given in mixture. It is included in the official list of the French Codex.

CYNANCHUM VINCETOXICUM. *R. Brown. Asclepias Vincetoxicum. Linn. White Swallow-wort. Vincetoxicum*. A perennial herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence gave origin to the officinal name. It has a bitterish acrid taste, and when fresh, a disagreeable odour which is diminished by drying. Taken internally, especially in the recent state, it excites vomiting, and is capable in large quantities of producing dangerous if not fatal inflammation of the stomach. Its former reputation as alexipharmic was wholly without foundation. It is said to be useful in cutaneous diseases, scrofula, &c.; but is little employed. The leaves of the plant also are emetic. Feneulle found in the root a peculiar principle analogous to emetin.

CYNOGLOSSUM OFFICINALE. *Hound's Tongue*. A biennial plant, common both in Europe and this country, and named from the shape of its leaves. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odour resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Different opinions as to its powers have been entertained, some considering it as nearly inert, others as a dangerous poison; nor has the difference been hitherto settled. Hound's tongue has been used as a demulcent and sedative in coughs, catarrh, spitting of blood, dysentery, and diarrhoea: and has been applied externally in burns, ulcers, scrofulous tumours, and goitre. The *pilulæ de cynogloss*, which are officinal in some parts of Europe, though they contain a portion of the root of hound's tongue, owe their properties chiefly to opium.

DIAPHORETIC ANTIMONY. *Antimonium Diaphoreticum. White Oxide of Antimony. Potassæ Biantimonias*. This compound is directed to be formed in the French Codex by deflagrating in a red-hot crucible, and keeping red-hot for half an hour, a mixture of pure antimony with twice its weight of nitrate of potassa, both being in fine powder. The product is washed with water and dried, and forms the *washed diaphoretic antimony*. As thus prepared, M. Oscar Figuiet has shown that it contains both sesquioxide of antimony and antimonious acid, and probably not in constant proportions, the nitre not being in sufficient quantity completely to peroxidize the antimony. When, however, the antimony is deflagrated with three times its weight of nitre, and the matter is kept at a red heat for an hour and a half, the whole of the antimony is converted into antimonious acid, and, when the product is thoroughly exhausted by boiling water, the solution obtained contains a large quantity of neutral antimoniate of potassa, and the insoluble residue is impure biantimoniate. M. Figuiet rejects this residue, which forms the diaphoretic antimony of the ordinary process, and obtains the preparation from the solution of the neutral antimoniate, by passing through it a stream of carbonic acid gas, which takes away one eq. of potassa from two of the antimoniate, and throws down the biantimoniate in the form of a white powder. M. Figuiet, by this process, obtained a quantity of the preparation, equal to three-fourths of the weight of the materials employed.

Diaphoretic antimony is a perfectly white powder. When properly prepared, as by the process of M. Figuier, it consists of two eqs. of antimoniac acid, one of potassa, and six of water. The dose of this preparation is two or three drachms. On account of its weak and variable nature, it has been very properly laid aside in practice.

DICTAMUS ALBUS. *White Fraxinella. Bastard Dittany.* This is a perennial European plant, the root of which is bitter and aromatic, and has been used as an anthelmintic, emmenagogue, and stomachic tonic, though at present little employed in Europe, and not at all in this country. Störck gave it in intermittents, worms, amenorrhœa, hysteria, epilepsy, and other nervous diseases. The bark of the root is the most active part. The dose in powder is from twenty grains to a drachm or more.

DIPPEL'S ANIMAL OIL. *Oleum Cornu Cervi.* This oil is obtained during the distillation of animal matters, in the processes for obtaining the ammoniacal products on a large scale. That portion which first comes over is pale yellow; but, in the progress of the distillation, it becomes gradually deeper coloured and thicker, and at last black and viscid. It is purified and rendered colourless by redistillation, a pyrogenous resin being left behind. Thus rectified it is a colourless liquid, very limpid and volatile, and having a penetrating, extremely fetid odour, and burning taste. By repeating the distillation till a dark residuum is no longer left in the retort, it may be obtained free from fetor, and of an agreeable, aromatic odour; and in this mode it is said to have been prepared by Dippel. Four or five distillations are necessary to this end. (*Am. Journ. of Pharm.* ix. 244.) The oil is soon altered by the action of air and light, becoming thick, yellow, brown, and finally black. It possesses an alkaline reaction, and probably contains the various principles which have been discovered by Reichenbach in the results of the distillation of organic substances.

This oil was formerly much used in medicine, but its repulsive odour and taste, as it is ordinarily prepared, have caused it to be almost entirely laid aside. It acts, in the dose of a few drops, given with water, as a stimulant and antispasmodic. Its presence in the spirit and salt of hartshorn gives to these preparations medicinal properties different from those of the pure carbonate of ammonia.

DIRCA PALUSTRIS. *Leather Wood.* An indigenous shrub, usually very small, but sometimes attaining the height of five or six feet, growing in boggy woods, and other low wet places, in almost all parts of the United States, though less abundantly in the western than in the eastern section. The berries, which are small, oval, and of an orange colour, are said to be narcotic and poisonous. The bark is the part which has attracted most attention. It is extremely tough, and of very difficult pulverization. In the fresh state it has a peculiar rather nauseous odour, and an unpleasant acrid taste, and when chewed excites a flow of saliva. It yields its acrimony completely to alcohol, but imperfectly to water even by decoction. In the dose of six or eight grains, the fresh bark produces violent vomiting, preceded by a sense of heat in the stomach, and often followed by purging. Applied to the skin it excites redness, and ultimately vesicates; but its epispastic operation is very slow. It appears to be analogous in its properties to mezezon, to which it is also botanically allied, as the two barks are derived from plants belonging to the same natural order.

DRAGON'S BLOOD. *Sanguis Draconis.* This is a resinous substance obtained from the fruit of several species of *Calamus*, especially the *C. Rotang* and *C. Draco*, small palms, growing in the Molucca Islands and other parts of the East Indies. On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing, or shaking in a bag, or by exposure to the vapour of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms; sometimes in small *oval masses*, of a size varying from that of a hazlenut to that of a walnut, covered with the leaves of the plant, and connected together in a row like beads in a necklace; sometimes in *cylindrical sticks* eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. In both these forms, it is of a dark reddish-brown colour, opaque, and readily pulverizable, affording a fine scarlet powder. It sometimes comes also in the form of a reddish powder, and in small irregular fragments or tears. An inferior kind, said to be obtained by boiling the fruit in water, is in *flat circular cakes*, two or three inches in diameter and half an inch thick. This also yields a fine red powder. A fourth variety, much inferior even to the last mentioned, is in *large disks*, from six to twelve inches in diameter by an inch in thickness, mixed with various impurities, as pieces of the shell, stem, &c., and supposed to be derived from the fruit by decoction with expression. A substance known by the

name of Dragon's blood is also derived by exudation from the trunk of the *Dracæna Draco*, a large tree inhabiting the Canary Islands and the E. Indies, and another from the *Pterocarpus Draco*, a tree of the West Indies and South America, by incision into the bark. These last, however, are little known in commerce. According to Lieut. Wellstead, much dragon's blood is obtained, in the island of Socotra, by spontaneous exudation from a large tree, growing at a considerable elevation upon the mountains.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to Herberger, it consists of 90·7 parts of a red resin which he calls *draconin*, 2·0 of fixed oil, 3·0 of benzoic acid, 1·6 of oxalate of lime, and 3·7 of phosphate of lime. It was formerly used in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart colour to plasters, but is valued chiefly as an ingredient of paints and varnishes.

DUTCH PINK. A yellow or brownish-yellow paint, consisting of clay, or a mixture of clay and chalk, or carbonate of lime in the form of whiting, coloured by a decoction of woad, French berries, or birch leaves, with alum.

EMERY. A very hard mineral, the powder of which is capable of wearing down all other substances except the diamond. As found in commerce, it is said to be derived chiefly from the island of Naxos in the Grecian Archipelago. It is pulverized by grinding it in a steel mill; and the powder is kept in the shops of different degrees of fineness. It is used for polishing metals and hard stones.

EUPHRASIA OFFICINALIS. *Eyebright.* A small annual plant, common to Europe and the United States, without odour, and of a bitterish, astringent taste. It was formerly used in various complaints, and among the rest in disorders of the eyes, in which it was thought to be very efficacious, and in the treatment of which it is still popular in some countries. Its ordinary name arose from its supposed efficacy in improving vision. The probability is that it is nearly inert.

FERROCYANURET OF ZINC. *Zinci Ferrocyanuretum.* This compound is formed by double decomposition between hot solutions of ferrocyanuret of potassium (ferroprussiate of potassa) and sulphate of zinc. It is thrown down as a white powder. It has similar medical properties to those of the cyanuret, and is used in the same diseases. The dose is from one to four grains, given in pill.

FRENCH CHALK. A variety of indurated talc. It is compact, unctuous to the touch, of a greenish colour, glossy, somewhat translucent, soft and easily scratched, and leaves a silvery line when drawn over paper. It is used chiefly for marking cloth, &c., and for extracting grease spots.

FUCUS VESICULOSUS. *Sea-wrack. Bladder-wrack.* This was omitted by mistake in the first part of this work; for, though discarded by the London College in the last revision of their Pharmacopœia, it is still retained by the Dublin College. It belongs to *Cryptogamia Algæ* in the sexual system, and to the natural order Algacæ. The following is the generic character. "MALE. *Vesicles* smooth, hollow, with villose hairs within, interwoven. FEMALE. *Vesicles* smooth, filled with jelly, sprinkled with immersed grains, prominent at tip. *Seeds* solitary." This sea-weed is perennial, with the frond or leaf flat, smooth and glossy, from one to four feet high, from half an inch to an inch and a half broad, furnished with a midrib throughout its length, dichotomous, entire upon the margin, and of a dark olive-green colour. Small spherical vesicles, filled with air, are immersed in the frond near the midrib. The fruit consists of roundish, compressed receptacles, at the ends of the branches, filled with a clear tasteless mucus. The plant grows upon the shores of Europe and of this continent, attaching itself to the rocks by its expanded woody root. On the coast of Scotland and of France, it is much used in the preparation of kelp. It is also employed as a manure, and is mixed with the fodder of cattle.

The *Fucus vesiculosus* has a peculiar odour, and a nauseous saline taste. Several chemists have undertaken its analysis, but the results are by no means satisfactory. It contains a large quantity of soda in saline combination, and iodine according to Gaultier de Claubry, in the state of iodide of potassium. These ingredients remain in its ashes, and in the charcoal resulting from its exposure to heat in close vessels. This charcoal, which is sometimes called *Æthiops vegetabilis* or *vegetable ethiops*, has long had the reputation of a deobstruent, and been given in goitre and scrofulous swellings. Its virtues were formerly ascribed chiefly to the carbonate of soda, in which it abounds; but since the discovery of the medical properties of iodine, this has been considered as its most active ingredient. The mucus contained in the *vesi-*

cles was applied externally, with advantage, by Dr. Russel, as a resolvent in scrofulous tumours.

Other species of *Fucus* are in all probability possessed of similar properties. Many of them contain a gelatinous matter, and a saccharine principle analogous to mannite; and some are used as aliment in times of scarcity by the wretched inhabitants of the coasts where they are collected. The *F. Helminthocorton*, the *Gigartina Helminthocorton* of Greville, has some reputation in Europe as an anthelmintic. It is one of the ingredients in that mixture of marine plants which is sold in Europe under the name of *Corsican moss* or *helminthocorton*. This is used in the form of decoction, from four to six drachms being boiled in a pint of water, of which a wineglassful is given three times a day.

FUMARIA OFFICINALIS. *Fumitory.* A small annual European plant, naturalized in this country, growing in cultivated grounds, and flowering from May to August. It was formerly considerably employed as a medicine, and is still used in Europe. The leaves are the official part. They are inodorous, have a bitter saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract prepared by evaporating the expressed juice, or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. The plant, indeed, abounds in saline substances, and to these in connexion with its bitter extractive, are to be ascribed any medical virtues which it may possess. It is gently tonic, in large doses is said to be laxative and diuretic, and is thought, moreover, to exercise an alterative influence over the system. Both in ancient and modern times it has been esteemed as a valuable remedy in visceral obstructions, particularly those of the liver, in scorbutic affections, and in various troublesome eruptive diseases of the skin. Cullen speaks very favourably of its influence in these last complaints. He gave the expressed juice in the dose of two ounces twice a day. Others have prescribed it in much larger quantities. The leaves either fresh or dried may be used in decoction, without precise limitation as regards the dose. The inspissated juice and an extract of the dried leaves have also been employed, and are said to have all the virtues of the leaves themselves.

FUSTIC. A yellow dye-wood, obtained from the *Morus tinctoria* (*Broussonetia tinctoria*, Kunth), a tree growing in the West Indies and South America. It is not used in medicine or pharmacy. According to Bancroft, two different woods bear in England the name of fustic, one the product of the tree just mentioned, distinguished as *old fustic*, probably from the greater magnitude of the billets in which it is imported; the other derived from the *Rhus Cotinus* or *Venice sumach*, and called *young fustic*.

GALANGAL. *Galanga.* Two varieties of this drug are described by authors, the *galanga major* or *large galangal*, and the *galanga minor* or *small galangal*. They are considered by some as the roots of two distinct plants; but there is reason to believe that they are both derived from the *Maranta Galanga* of Linn., the *Alpinia Galanga* of Willd., and that they differ in consequence of the different stages of growth at which they are collected. They are brought from the East Indies. The *larger variety* is cylindrical, three or four inches long, as thick as the thumb or thicker, often forked, reddish-brown externally, slightly striated longitudinally, marked with whitish circular rings, orange-brown internally, rather hard and fibrous, difficultly pulverizable, of an agreeable aromatic odour, and a pungent, hot, spicy, permanent taste. The *small galangal* resembles the preceding in shape, but is smaller, not exceeding the little finger in thickness, of a darker colour, and of a stronger taste and smell. According to Morin, galangal contains a volatile oil, an acrid resin, extractive, gum, bassorin, and lignin. R. Brandes is said to have found a peculiar crystallizable substance called *kempferid*. (*Annal. der Pharm.* xxxii. 311.) The active principles are the volatile oil, and acrid resin. Its medical effects are those of a stimulant aromatic; and it may be used for the same purposes as ginger. It was known to the ancient Greeks and Arabians, and entered into numerous compound preparations, some of which have but recently passed out of use. At present the root is very seldom employed. Its dose is from fifteen to thirty grains in substance, and twice as much in infusion.

GALEGA OFFICINALIS. *Goat's Rue.* A perennial herb, growing in the South of Europe, and sometimes cultivated in gardens. It is without smell unless bruised, when it emits a disagreeable odour. Its taste is unpleasantly bitter and somewhat rough, and when chewed, it stains the saliva yellowish-brown. In former times it was much employed as a remedy in malignant fevers, the plague, the bites of serpents, worms, &c.; but it has now fallen into merited neglect. The roots of the *Galega Virginiana*, which is a native of the United States, are said to be diaphoretic and powerfully anthelmintic. They are given in decoction.

GALIAM APARINE. *Cleavers. Goose-grass.* This is an annual, succulent plant, common to Europe and the United States, growing in cultivated grounds, and along fences and hedges. It is inodorous, and has a bitterish, herbaceous, somewhat acrid taste. The expressed juice is said to be aperient, diuretic, and anti-scorbutic; and has been used in dropsy, congestion of the spleen, scrofula, and scorbutic eruptions. In the last complaint it has been thought peculiarly useful. Three ounces of the juice may be taken twice a day. The fresh herb, prepared in the form of ointment or of decoction, has been applied externally to scrofulous swellings with supposed advantage.

GALIAM VERUM. *Yellow Ladies Bed-straw. Cheese-rennet.* This species of Galium is perennial, and a native of Europe. The flowers, which are yellow, have a peculiar, agreeable odour, and have sometimes been given in nervous affections, with a view to their supposed antispasmodic powers. The herb is inodorous, but has an astringent, acidulous, bitterish taste. The property of coagulating milk was formerly ascribed to it, but is certainly not constant, as the experiment has been frequently tried without success. The bruised plant is sometimes used to colour cheese yellow, being introduced into the milk before coagulation. It is also used for dyeing yellow. The roots of this and of most other species dye red; and the plant eaten by animals colours the bones like madder. This species of Galium was formerly highly esteemed as a remedy in epilepsy and hysteria, and was applied externally in cutaneous eruptions. It may be employed either in the form of the recently expressed juice, or of a decoction prepared from the fresh plant. Its medical properties, however, are feeble.

Of the American species, the *G. tinctorium* is closely allied in properties to the *G. verum*. It is said to be useful in cutaneous diseases; and the root is employed by the Indians for staining their feathers and other ornaments red.

GENISTA TINCTORIA. *Dyer's Broom. Dyer's Weed. Green Weed.* A low shrub, growing wild in Europe, and sometimes cultivated in this country in gardens. The flowering tops of the plant are employed to dye a yellow colour, whence its name was derived. Both these and the seeds have been employed in medicine. It is said that they are purgative and even emetic, especially the seeds, which were formerly used as a cathartic in the dose of a drachm and a half. By some authors they are said to be diuretic, and to be useful in dropsy; but it may be a question whether they were not confounded with the seeds and tops of the common broom (*Cytisus Scoparius*). Attention was some years since attracted to the plant as a preventive of hydrophobia, for which purpose it was said to have been long used effectually by the peasants of Podolia, the Ukraine, and other provinces of Russia. It was employed in the form of very strong decoction, both internally and as an application to the bitten part; and its use was persevered in for six weeks; but the trials made with it in other parts of Europe have not justified the hopes which were at first entertained. The Russians are said to use it in connexion with the *Rhus coriaria*.

GERANIUM ROBERTIANUM. *Herb Robert.* This species of Geranium grows wild both in Europe and the United States, but is rare in this country; and Pursh states that the American plant is destitute of the heavy smell by which the European is so well known, though the two agree in all other respects. The herb has a disagreeable, bitterish, astringent taste, and imparts its virtues to boiling water. It has been used internally in intermittent fever, consumption, hemorrhages, nephritic complaints, jaundice, &c., has been employed as a gargle in affections of the throat, and has been applied externally as a resolvent to swollen breasts and other tumours.

GLASS OF ANTIMONY. *Vitrum Antimonii.* This is prepared from the sesquisulphuret of antimony by a partial roasting and subsequent fusion. The sesquisulphuret is reduced to coarse powder, and strewed upon a shallow, unglazed, earthen vessel, and heated gently and slowly, being continually stirred to prevent it from running into lumps. White vapours of sulphurous acid arise; and when these cease, the heat is increased a little to reproduce them. The roasting is continued in this manner until, at a red heat, no more vapours are given off. The matter is then melted in a crucible with an intense heat, and kept in a state of fusion until it assumes the appearance of melted glass, when it is poured out on a heated brass plate. In this process, part of the sulphur of the sesquisulphuret is driven off by the roasting; while that portion of the antimony which loses its sulphur becomes sesquioxide. The roasted matter, accordingly, consists of sesquioxide of antimony and undecomposed sesquisulphuret; and these, by uniting during the fusion, form the glass.

Properties. Glass of antimony is in thin irregular pieces, exhibiting a vitreous frac-

ture, and having a metallic steel-gray lustre. When well prepared it is transparent, and, upon being held between the eye and the light, appears of a rich orange-red, or garnet colour; but if of inferior quality it is black and opaque. It is hard and brittle, and rings when struck with a hard substance. It is insoluble in water, but soluble in acids and in cream of tartar, with the exception of a few red flocculi. Its essential constituents are the sesquioxide and sesquisulphuret united in variable proportions. When of good quality it consists of about eight parts of sesquioxide to one of sesquisulphuret. It usually contains about five per cent. of silica, and three of sesquioxide of iron, which are derived from the crucible, and to the former of which the vitrification of the product is owing. When good, it is dissolved, with the exception of a few red flocculi, in strong muriatic acid. An excess of silica is known by the acid leaving a gelatinous residuum, and the iron may be detected by ferrocyanuret of potassium, and its amount judged of by the bulk of the precipitate and the depth of its blue colour. Sometimes glass of lead is sold for glass of antimony; a fraud easily detected by the difference in sp. gr. between the two substances; the glass of lead having a density of nearly seven, while that of glass of antimony is not quite five. The London College formerly employed the glass of antimony for making tartar emetic; but in the last London Pharmacopœia it has been dismissed from the official list, on account of the difficulty of obtaining it, and its liability to adulteration.

Medical Properties, &c. Glass of antimony is an active antimonial; but, owing to its variable composition and uncertain operation, is at present very seldom used. When the levigated powder is mixed with one-eighth of its weight of melted yellow wax, and the mixture roasted over a slow fire, with constant stirring, until it ceases to exhale vapours, a coal-like pulverizable mass is formed, which is the *cerated glass of antimony*, a preparation formerly included in the Edinburgh Pharmacopœia.

GLECHOMA HEDERACEA. *Nepeta Glechoma.* *Ground-ivy.* A small perennial herb, indigenous in Europe and the United States, and growing in shady grassy places, as in orchards, and along fences and hedges. It belongs to the family of labiate plants, and shares their general properties. The herb was formerly officinal, and still enjoys some credit as a domestic remedy. It has a peculiar disagreeable odour, and a bitterish, rough, somewhat aromatic taste, and imparts its properties to boiling water. From the statements of authors it appears to be gently stimulant and tonic, with perhaps, a peculiar direction to the lungs and kidneys. It has also been considered aperient. The complaints in which it has been most used are chronic affections of the pulmonary and urinary organs; and at one time it had considerable reputation as a remedy in consumption. It has also been employed as a vulnerary and errhine. The usual form in which it was administered was that of infusion, of which a quantity was given for a dose containing the virtues of half a drachm or a drachm of the herb.

GLUE. An impure form of gelatin, obtained from various animal substances by boiling them in water, straining the solution, and evaporating it till upon cooling it assumes the consistence of jelly. The soft mass which results is then divided into thin slices, which are dried in the open air. Glue, when of good quality, is hard and brittle, of a brown colour, and equally transparent throughout. It softens and swells up very much in cold water, without dissolving; but is readily dissolved by hot water. It is employed chiefly for cementing pieces of wood together, being too impure for the purposes of a test, or for internal use.

Capsules of gelatin. Glue has within a few years been applied to an important practical purpose in pharmacy. Certain medicines are so offensive to the taste, and consequently so apt to sicken the stomach, that it is an object of importance to administer them in such a way as to prevent their contact with the tongue and palate. This object is fully accomplished, so far as regards many disagreeable liquid medicines, by the use of the *capsules of gelatin*, invented by M. Dublanc of Paris. These are prepared from the purest glue in the following manner. Small pouches made of fine skin, of an oval form, are attached by a waxed thread to the smaller extremity of a hollow elongated metallic cone, which is bent towards its point, and has its base closed by a cover which is screwed on so as to make the instrument air-tight. Into this conical tube sufficient mercury is poured to fill the pouch, which, thus distended, is dipped into a concentrated sweetened solution of glue, and afterwards exposed to heat in a vertical position, so as to dry the layer of gelatin which it has received. In the same manner a second coating may be given, and the process again repeated till a sufficient thickness has been obtained. The cone being then reversed, the mercury flows out of the pouch, which collapses, and allows the capsule of gelatin to be removed. Into this the medicine may now be introduced, care being taken to avoid any contact with the outer surface of the capsule. The opening is next to be closed

by means of a thin lamina of gelatin previously softened by steam; and a solution of the same substance should be applied to the edges by means of a camel's hair pencil. Another mode of preparing the capsules is as follows. Take a cylinder of iron or hard wood, four lines in diameter and a few inches long, and smoothly rounded at the end. Dip half an inch of this end first into a saturated warm alcoholic solution of soap, and afterwards, when the soap has concreted upon the surface, into a concentrated hot solution of gelatin, and repeat the latter immersion once or oftener if it be desired to have a firm capsule. When the glue has concreted, remove the capsule. A top for it may be made in the same way, and, after the body has been filled with the liquid to be given, is to be applied and secured by rubbing a camel's hair pencil moistened with hot water over the line of junction. (*Med. Exam.* N. S. i. 441.)

The demand for these capsules was at first supplied exclusively from abroad, but they are now prepared largely in this country, and according to various processes. For an account of one of these, invented and described by Mr. Alfred Guillou of Philadelphia, the reader is referred to the *American Journal of Pharmacy*, vol. ix. p. 20. The capsules may be made of such a capacity as to contain from ten to fifteen grains of copaiba.

GNAPHALIUM MARGARITACEUM. *Cudweed. Life-everlasting.* An indigenous herbaceous perennial, growing in fields and woods, and flowering in August. The herb of this and of the *G. polycephalum*, or *sweet-scented life-everlasting*, is sometimes used in the form of tea by the country people, in diseases of the chest and of the bowels, and in hemorrhagic affections, and externally, in the way of fomentation, in bruises, languid tumours, and other local complaints; but it probably possesses little medical virtue. Shoepf says that it is anodyne. In Europe, different species of *Gnaphalium* are also occasionally employed for similar purposes.

GOLD. *Aurum.* The preparations of this metal were introduced to the notice of physicians by Dr. Chrestien of Montpellier in 1810. They are employed both internally, and by frictions on the tongue and gums. The principal affections in which they have been recommended are secondary syphilis, syphilitic ulcerations, scrofula, and inveterate eruptions, particularly those of a leprous character. The chief preparations which have been used up to the present time are metallic gold in a finely divided state, the oxide (*teroxide* or *auric acid*), the chloride (*terchloride*), the iodide, the double chloride of gold and sodium, the chloroaurate of ammonia (a compound of *terchloride* of gold and muriate of ammonia), and the cyanuret (*tercyanuret*) of gold. *Gold in powder* may be obtained by rubbing up gold-leaf with 10 or 12 times its weight of sulphate of potassa until brilliant particles are no longer visible, and then washing away the sulphate with boiling water. The *oxide* may be procured by treating the nitro-muriatic solution of gold with an excess of magnesia, and washing the precipitate, first with water, and afterwards with dilute nitric acid. The *chloride* is obtained by dissolving pure gold in three times its weight of nitro-muriatic acid, by the aid of a moderate heat. The solution is evaporated by a gentle heat nearly to dryness, being at the same time stirred with a glass rod. It is in the form of a crystalline mass of a deep red colour. Its solution has a fine yellow tint. Being deliquescent, it requires to be kept in ground stoppered bottles. The *iodide* may be made by precipitating a solution of the *terchloride* of gold by one of iodide of potassium, and washing the precipitate with alcohol to remove the excess of iodine. It is of a greenish-yellow colour, and, when heated in a porcelain crucible, is resolved into iodine vapours and a residue of pure gold. The *chloride of gold and sodium* is prepared by dissolving four parts of gold in nitro-muriatic acid, evaporating the solution to dryness, and dissolving the dry mass in eight times its weight of distilled water. To this solution one part of pure decrepitated common salt is added, previously dissolved in four parts of water. The mixed solution is then evaporated to dryness, being in the mean time constantly stirred with a glass rod. This salt is of a golden yellow colour, and, when crystallized, is in the form of long prismatic crystals, unalterable in the air. The *chloroaurate of ammonia* is formed by dissolving one part of the *terchloride* of gold and two parts of muriate of ammonia in distilled water, assisted by a few drops of nitro-muriatic acid, and evaporating the solution to dryness by a gentle heat. The *cyanuret* is best obtained, according to M. Oscar Figuier, as follows. Prepare the chloride of gold as neutral as possible by repeated solutions and crystallizations; and to the solution of this salt add, very cautiously, avoiding any excess, a solution of pure cyanuret of potassium, so long as any precipitate falls. The precipitate, consisting of cyanuret of gold, is to be washed with pure water, and dried in the dark. The solution of the cyanuret of potassium may be obtained pure and free

from formiate and carbonate of potassa, by dissolving in water, soon after its preparation and before it has had time to undergo any change, the residue obtained by calcining the yellow ferrocyanuret of potassium. Of these preparations gold in powder, and the oxide, chloride, iodide, double chloride, and cyanuret are official in the French Codex.

The preparations of gold are decidedly poisonous, though in different degrees. The chloride is most virulent, and, according to Dr. Chrestien, is even more active than corrosive sublimate. In an overdose, it produces pain, inflammation, and even ulceration of the stomach and bowels, and otherwise acts as a corrosive poison. The general effects of these preparations, in moderate doses, is to produce increased fulness and frequency of the pulse, and to augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels; but if the dose is pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

Metallic gold, the oxide, chloride, and iodide are not as much used as the double chloride of gold and sodium. The oxide may be given, in the form of pill, in the dose of a tenth of a grain, in scrofula, and lymphatic swellings, beginning with one pill daily, and afterwards gradually increasing to seven or eight in the 24 hours. The iodide is given in the same cases in which the other preparations of gold are administered. The dose is from the fifteenth to the tenth of a grain.

The *chloride of gold and sodium* is the preparation of gold most commonly employed. It may be given in lozenges, each containing the twelfth of a grain, by mixing intimately five grains of the salt with an ounce of powdered sugar, and making the whole with mucilage of tragacanth into a proper mass to be divided into sixty lozenges. Pills, containing the same dose, may be formed by dissolving ten grains of the dried salt in a drachm of distilled water, and forming the solution into a pilular mass with a mixture of four drachms of potato starch and one drachm of gum arabic, to be divided into one hundred and twenty pills. (*Journ. de Pharm.* xx. 648.) For frictions on the gums and tongue, Chrestien recommends the following formula:—Crystallized chloride of gold and sodium, one grain; powdered orris root, deprived of its soluble parts by alcohol and water and dried, two grains. Mix. At first the fifteenth part of this powder is used daily by frictions; afterwards the fourteenth, the thirteenth, &c. until, increasing gradually, the tenth or eighth part is employed. The use of four grains of the salt in this way is said commonly to cure bad cases of recent syphilis, such, for example, as are characterized by the co-existence of chancres, warts, and buboes. In the preparation of this powder, lycopodium may be substituted with advantage for the orris.

The *chloroaurate of ammonia* has been recommended by Bouchardat in amenorrhœa and dysmenorrhœa in debilitated subjects, in the dose of about the tenth of a grain. A grain may be dissolved in five teaspoonfuls of alcohol and five of water, and a teaspoonful given morning and evening, mixed with sweetened water.

The *cyanuret of gold* is employed, like the chloride of gold and sodium, mixed with inert powders in frictions, and in the form of pill. The fifteenth of a grain may be rubbed into the gums daily for fifteen days, next the fourteenth of a grain for fourteen days, and so on, increasing until the dose amounts to the ninth or eighth of a grain. The dose for internal exhibition is the eighteenth of a grain, gradually increased to the eighth of a grain. The cyanuret of gold has been found useful in the treatment of syphilis and scrofula by M. Pourché, and is said to be less exciting than the double chloride, when used in those diseases. (*Journ. de Pharm.* xx. 599 et 649.)

The different medicinal compounds of gold should not be prepared in pill, powder, or otherwise, until they are wanted for use; as they are liable to undergo decomposition when kept. They should be carefully secluded from the light.

GRATIOLA OFFICINALIS. *Hedge Hyssop.* This is a perennial herb, with an erect quadrangular stem, about a foot in height, furnished with opposite, sessile, lanceolate, somewhat serrate leaves, and solitary, peduncled, axillary flowers. It is a native of the South of Europe, where it flourishes in meadows and other moist grounds. The whole herb is used. It is nearly inodorous, but has a bitter nauseous taste. Both water and alcohol extract its active properties. It is a drastic cathartic and emetic, possessing also diuretic properties, and is employed on the continent of Europe in dropsy, jaundice, worms, chronic hepatic affections, scrofula, and various other complaints. With us it is almost unknown as a remedy. The dose of the powdered herb is from fifteen to thirty grains; of the infusion, made in the proportion of half an ounce to the pint of boiling water, half a fluidounce.

HAMAMELIS VIRGINICA. *Witch-hazel.* An indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and frequently on the banks of streams. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue till the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazel-nut, ripens in the following autumn, and is often mingled on the same plant with the new blossoms. The bark has a bitter, astringent, somewhat sweetish and pungent taste. It appears to have attracted notice as a remedy employed by the Indians, who are said to have applied it as a sedative and discutient to painful tumours, and other cases of external inflammation. It is used in the shape of poultice, or as a wash in the form of decoction, in hemorrhoidal affections and ophthalmia. The leaves are said to possess similar properties, and, in the state of infusion, to be given internally in bowel complaints and hemorrhages. The seeds are black and shining externally, white, oily, and farinaceous within, and are edible like the hazelnut.

HEDERA HELIX. *Ivy.* This well known evergreen creeper is a native of Europe. The fresh leaves have a balsamic odour, especially when rubbed, and a bitterish, harsh, unpleasant taste. They are used externally for dressing issues, and, in the form of decoction, have been recommended in sanious ulcers and cutaneous eruptions, particularly tetter and the itch. Dried and powdered, they have been employed in the atrophy of children, and in complaints of the lungs, in the dose of a scruple or more. The berries, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. MM. Vandamme and Chevallier have announced the existence in ivy seeds of a peculiar alkaline principle, which they propose to call *hederin* (*hederia*). It is very bitter, and appears to be closely allied to quinia in febrifuge properties. It is obtained by treating the seeds with hydrate of lime, dissolving the precipitated alkali in boiling alcohol, and evaporating the alcoholic solution. (*Am. Journ. of Pharm.* xiii. 172, from the *Journ. de Chim. Med.*) From the trunks of old ivy plants, growing in the South of Europe and the North of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of *ivy gum*. It is in pieces of various sizes, of a dark yellowish-brown colour sometimes inclining to orange, more or less transparent, sometimes of a deep ruby-red colour internally, of a vitreous fracture, pulverizable, yielding a lively orange-yellow powder, of a peculiar not disagreeable odour when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces contain a considerable proportion of bassorin, and others large quantities of ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve toothache. The wood of the ivy, which is light and porous, is sometimes used for making *issue-peaus*.

HELENIUM AUTUMNALE. *False Sunflower. Sneezewort.* An indigenous perennial herbaceous plant, from three to seven feet high, with large golden-yellow compound flowers, which appear in August. It grows in all parts of the United States, flourishing best in meadows, moist fields, and other low grounds. All parts of it are bitter and somewhat acrid, and, when snuffed up the nostrils in the state of powder, produce violent sneezing. The leaves and flowers have been recommended as an excellent errhine. Clayton says that the plant is thought to be useful in intermittent fevers.

HELLEBORUS FŒTIDUS. *Bears-foot.* This is a perennial European plant, growing under hedges and in shady places, and flowering in March and April. It derived its botanical designation from the offensive odour which it exhales. The leaves are the part used. Their taste is bitterish, pungent, and acrid; and when chewed they excoriate the mouth. The footstalks are even more acrid than the leaves themselves. The plant has not been analyzed. This species of hellebore is said by Allioni to be the most acrid and energetic of all the plants belonging to the genus. It is powerfully emetic and cathartic, and in very large doses produces dangerous effects. It has long been used in Great Britain as a domestic remedy for worms, and was brought before the notice of the profession by Dr. Bisset. This physician found it a very efficacious anthelmintic, and prescribed it also in asthma, hysteria, and hypochondriasis. M. Decerfs has known it to cause the expulsion of tænia. It is given in powder or decoction. The dose for a child from two to six years old is from five grains to a scruple of the dried leaves, or a fluidounce of the decoction made by boiling a drachm of the dried leaves in half a pint of water. This quantity should be repeated morning and night for two or three days in succession. A syrup made

from the juice of the green leaves is used in England. The remedy is scarcely known in the United States.

HEMIDESMUS INDICUS. R. Brown. *Periploca Indica*, Willd. *Asclepias pseudo-sarsa*, Roxburgh. *Indian Sarsaparilla*. A climbing asclepiadaceous plant, growing in all parts of the peninsula of Hindostan. The root is long, slender, tortuous, cylindrical, and little branched; consisting of a ligneous centre, and a brownish corky bark, which is marked with longitudinal furrows and transverse fissures. It has a peculiar aromatic odour, and a bitterish taste. M. Garden obtained from it a peculiar volatilizable principle with acid properties, which he named *smilasperic acid*, under the erroneous impression that the root was derived from the *Smilax aspera*. Pereira proposes for it the name of *hemidesmic acid*. It is probably the active principle. It is used in India as a substitute for sarsaparilla, and has been introduced into Great Britain. In some instances it is said to have proved successful in syphilis, when that medicine has failed; though it cannot be relied upon. The native practitioners in India are said to employ it in nephritic complaints, and in the sore mouth of children. It is given in infusion or decoction, made in the proportion of two ounces of the root to a pint of water. A pint may be given, in wineglassful doses, in the course of a day.

HERMODACTYLS. *Hermodactyli*. Under this name are sold in the shops of Europe the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is considered a species of *Colchicum*, and the *C. variegatum*, a native of the South of Europe and the Levant, is particularly indicated by Fée, Geiger, and others; while by authors not less eminent, the roots are confidently referred to the *Iris tuberosa*. They certainly bear a considerable resemblance to the bulb of the *Colchicum autumnale*, being heart-shaped, channeled on one side, convex on the other, and from half an inch to an inch in length, by nearly as much in breadth. As found in the shops, they are destitute of their outer coat, of a dirty yellowish or brownish colour externally, white and amylaceous within, inodorous, and nearly tasteless, though sometimes slightly acrid. They are often worm-eaten. Their chief constituent is starch, and they contain no veratria or colchicia. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of *Colchicum*; but Geiger observes that they may have lost their acrimony by age. They are in fact almost without action upon the system, and are now seldom used; never, we believe, in this country. It is doubted whether they are the *hermodactyli* of the ancients, which were certainly a powerful medicine, operating very much in the same manner with our colchicum, and like it proving useful in gout and rheumatism. Pereira describes a bitter variety of hermodactyls, which was brought from India by Dr. Royle. The bulbs are smaller than the others, of a darker colour, and have externally a striped or reticulated appearance. From their bitter taste they are probably more active also as a medicine.

HIBISCUS ABELMOSCHUS. *Abelmoschus moschatus*, Wight and Arnott. An evergreen shrub, growing in Egypt, and in the East and West Indies, and affording the seeds known under the name of *semen Abelmoschi*, *alceæ Egyptiacæ*, and *grana moschata*. These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown colour, of an odour like that of musk, and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic; but are now used only in perfumery. The Arabs flavour their coffee with them. They are said to be sometimes employed in the adulteration of musk. Another species, the *Hibiscus esculentus* or *Abelmoschus esculentus* of Wight and Arnott, is cultivated, under the name of *okra*, *bendee*, or *gombo*, in various parts of the world, for the sake of its fruit, which abounds in mucilage, and is much employed for thickening soup. The leaves are sometimes employed for preparing emollient poultices.

HYDRASTIS CANADENSIS. *Yellow Root. Orange Root*. This is an indigenous plant, growing in different parts of the United States, but most abundantly beyond the Alleghanies. It flourishes best in rich shady woods. It has a perennial root, and an herbaceous stem, from six inches to a foot high, with two unequal leaves, and a single terminal whitish or rose-coloured flower. The root consists of a tortuous caudex, and numerous long fibres, and is of a bright yellow colour. It is juicy in the recent state, and loses much of its weight when dried. It has a strong, somewhat narcotic odour, and an exceedingly bitter taste. It probably possesses the ordinary virtues of the vegetable bitters, and is said to be popularly employed as a tonic in some parts of the country. In the form of infusion, it has been used in the Western States as a

topical application in ophthalmia; and the Indians are said to employ it in the same manner in old ulcers of the legs. The notion of its efficacy in cancer, originating in a report which reached the late Professor Barton, that it was used in the cure of this complaint by the Cherokees, is probably altogether groundless. The Indians employ the juice of the root to stain their clothing, &c., yellow.

HYDRIODIC ACID. *Acidum Hydriodicum.* Dr. Andrew Buchanan, of Glasgow, recommends the following formula for obtaining this acid for medicinal purposes. Take of iodide of potassium 330 grains, tartaric acid 264 grains. Dissolve the salts, separately, each in a fluidounce and a half of distilled water, and mix the solutions. Filter the liquor, in order to separate the bitartrate of potassa which precipitates, and add to it sufficient distilled water to make the whole measure fifty fluidrachms. When of this strength, each fluidrachm of the acid contains five grains of iodine. The solution of hydriodic acid, when thus prepared, is sufficiently pure for medicinal use, although containing a little cream of tartar in solution. At first it is limpid, or has only a slight yellow tinge; but on keeping it assumes, first a wine-yellow, and afterwards a beautiful red colour, in consequence of the disengagement of free iodine.

Dr. Buchanan considers the effects of uncombined iodine to be those of an irritant, and its alterative powers, when these are manifested, to depend upon its conversion into hydriodic acid, of a strength sufficiently moderate to be readily absorbed, and to pass into the current of the circulation. He conceives that when iodine is given, and proves to be absorbed, it is by being first converted into hydriodic acid by hydrogen derived from the gastric juices, or from the tissues of the stomach, which latter undergo corrosion. A desire to avoid this incidental irritant effect led Dr. Buchanan at first to combine the iodine with starch, which he supposes to furnish the necessary hydrogen while undergoing digestion, and finally to use the hydriodic acid ready formed.

In giving the liquid hydriodic acid according to his formula, Dr. Buchanan begins by exhibiting a few drops, and afterwards increases the dose first to a fluidrachm and finally to half a fluidounce three times a day, equal to a drachm of iodine daily. This was his ordinary maximum dose, but sometimes he gave a fluidounce three times a day. In all cases the acid was administered sufficiently diluted with water to reduce it to an agreeable sourness, in which state it possesses no irritant action whatever. When, however, the acid has undergone a change of colour, as previously mentioned, Dr. Buchanan uses a solution of starch as a vehicle, in order to divest the free iodine, the presence of which is indicated by this change, of all irritant qualities. Hydriodic acid, when thus used, exhibits the same therapeutic effects as free iodine, with the advantages of having no irritant property, and of affording the means of introducing much larger quantities of iodine into the system through the medium of absorption, than when given in the ordinary form. (*Am. Journ. of Med. Sci.* xx. 210, and 214, from the *Med. Gazette*.)

HYDROCYANIC ETHER. *Æther Hydrocyanicus. Hydrocyanate of Etherine. Cyanuret of Ethule.* This ether was discovered by Pelouze. It is formed by distilling a mixture of sulphovinate of baryta and cyanuret of potassium. It is a colourless liquid of a penetrating garlic odour, soluble in alcohol and ether, sparingly soluble in water, boiling at 180°, and weighing specifically 0.78. It is very poisonous, but less so than hydrocyanic acid, with which it agrees in therapeutic action and dose.

HYPERICUM PERFORATUM. *St. John's Wort.* A perennial herb, abundant both in Europe and in this country, often covering whole fields, and proving extremely troublesome to farmers. It is usually from one to two feet high, with leaves, which, from the presence of numerous transparent vesicles, appear as if perforated, and have hence given origin to the botanical designation of the plant. The flowers, which are numerous and of a deep yellow colour, appear during the summer from June to August. The flowering summits are the part used, though the unripe capsules are possessed of the virtues of the plant in an equal degree, and the seeds are said to be even stronger. St. John's wort has a peculiar balsamic odour, which is rendered more sensible by rubbing or bruising the plant. Its taste is bitter, resinous, and somewhat astringent. It imparts a yellow colour to cold water, and reddens alcohol and the fixed oils. Its chief constituents are volatile oil, a resinous substance, tannin, and colouring matter. As a medicine, it was in high repute among the ancients, and was much employed by the earlier modern physicians. Among the complaints for which it was used, were hysteria, mania, intermittent fever, dysentery, gravel, hemorrhages, pectoral complaints, worms, and jaundice; but it was, perhaps, most highly esteemed as a remedy in wounds and bruises, for which it was employed both internally and externally. It is difficult to ascertain its exact value as a remedy; but from its sen-

sible properties, and from the character of the complaints in which it has been thought useful, it may be considered, independently of its astringency, as somewhat analogous in medical power to the turpentine. It formerly enjoyed great reputation for the cure of demoniacs; and the superstition still lingers among the vulgar in some countries. At present the plant is scarcely used except as a domestic remedy. The summits were formerly given in the dose of two drachms or more. A preparation was at one time officinal, under the name of *oleum hyperici*, made by treating them with a fixed oil. It has a red colour, and is still used in many families as a sovereign remedy for bruises.

HYSSOPUS OFFICINALIS. *Hyssop.* This is a labiate plant, belonging to the class and order Didynamia Gymnospermia of the sexual system. It is perennial, with numerous erect, quadrangular, somewhat branching stems, which are woody in their inferior portion, about two feet high, and furnished with opposite, sessile, lanceolate linear, pointed, punctate leaves. The flowers are violet coloured or blue, sometimes white, turned chiefly to one side, and arranged in half verticillated, terminal, leafy spikes. The upper lip of the corolla is roundish and notched at the apex, the lower is divided into three segments, of which the undermost is obovate.

Common hyssop is a native of the continent of Europe, where, as well as in this country, it is also cultivated in gardens. The flowering summits and leaves are the parts used. They have an agreeable aromatic odour, and a warm, pungent, bitterish taste. These properties they owe to an essential oil, which may be obtained separate by distillation with water, and rises also with alcohol. Hyssop is a warm gently stimulant aromatic, applicable to the same cases with the other labiate plants. Its infusion has been much employed in chronic catarrhs, especially in old people, and those of a debilitated habit of body. It acts by facilitating expectoration of the mucus which is too abundantly secreted. In this country, however, it is very seldom used by regular practitioners. The Edinburgh College discarded it at the last revision of their Pharmacopœia.

ILEX. *Holly.* Several species of this genus of plants are employed in different parts of the world. The *I. Aquifolium*, or *common European holly*, has attracted much attention in France. It is usually a shrub, but in some places attains the magnitude of a middling-sized tree. Different parts of it are used. The viscid substance called birdlime is prepared from the *inner bark*. The *leaves*, which are of a bitter, somewhat austere taste, were formerly much esteemed. They were considered diaphoretic, and in the form of infusion were employed in catarrh, pleurisy, small-pox, gout, &c. Within a few years they have gained some reputation in France as a cure for intermittents, being considered by some as equal, if not superior to Peruvian bark; but the first reports in their favour have not been fully confirmed. They were used in the form of powder, in the dose of a drachm two hours before the paroxysm; and this dose was sometimes repeated frequently in the apyrexia. Their febrifuge virtues are said to depend on a peculiar bitter principle, for which the name of *ilicin* has been proposed. The *berries* are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels and sometimes vomit. Their expressed juice has been used in jaundice.

The *Ilex opaca*, or *American holly*, is a middling-sized evergreen tree, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It is so similar to the European plant, that it is, by some writers, considered as the same species. It is said to possess the same medical properties.

The *Ilex Paraguaiensis*, or *I. Mate* of St. Hilaire, is the plant which yields the celebrated *Paraguay tea*, so extensively consumed as a beverage in the interior of South America. The leaves, which are the part used, have a balsamic odour, and a bitter taste, and are usually at first disagreeable to the palate. They have a pleasant corroborant effect upon the stomach; but, when very largely taken, are said to purge and vomit. They are used in the form of infusion.

The *Ilex vomitoria* of Aiton and Linn., the *I. Cassina* of Michaux, is a handsome evergreen shrub, growing in our Southern States, and especially abundant along the southern coast of Florida. It is the *cassina* of the Indians, who formerly employed a decoction made from the toasted leaves, called *black drink*, both as a medicine, and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the *Ilex Dahoon* of Walter and Michaux have similar properties, and are also said to have entered into the composition of the black drink.

ILLICIUM FLORIDANUM. *Florida Anise-tree.* This is an evergreen shrub or small tree, growing in Florida, along the coast which bounds the Gulf of Mexico. The bark, leaves, and probably also the seed vessels, are endowed with a spicy odour and taste analogous to anise, and might, perhaps, be used for the same purposes as

this aromatic. It is a question worthy of investigation, whether the capsules of this plant might not be substituted for those of the *Illicium anisatum* or *star aniseed*, which yield much of the oil used in this country under the name of *oil of anise*. (See *Anisum*.) Another species of *Illicium*, the *I. parviflorum*, a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavour closely resembling that of *sassafras* root.

IMPATIENS FULVA and IMPATIENS PALLIDA. *Touch-me-not. Jewel-weed. Balsam-weed.* These two species of *Impatiens*, considered by Michaux as varieties of the *I. Nolitangere* of Linnæus, are indigenous, annual, succulent plants, from two to four feet high, growing in low moist grounds in all parts of the Union, and flowering in July and August. They may be known by their tender, juicy, almost transparent stems; by their yellow flowers, which in one species are pale and sparingly punctate, in the other, are deeper coloured and crowded with dark spots; and by their capsules, which burst elastically and curl up with the slightest pressure. They probably possess properties similar to those of the *I. Nolitangere* of Europe, which has an acrid burning taste, and when taken internally, acts as an emetic, cathartic, and diuretic, though considered a dangerous plant, and therefore little used. Dr. Ruan, of Philadelphia, has informed us that he has employed with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing a yellow colour. The *I. Balsamina* or *balsam-weed, touch-me-not, &c.*, of the gardens, is said to possess similar properties with the other species.

IMPERATORIA OSTRUTHIUM. *Masterwort.* An umbelliferous plant, indigenous in the South of Europe. The root has a strong odour, similar to that of angelica, and a pungent, biting, aromatic taste, attended with a flow of saliva, and followed by a glowing warmth which remains long in the mouth. It was formerly considered alexipharmic, stomachic, corroborant, emmenagogue, diuretic, and diaphoretic; and was used in a wide circle of complaints with so much supposed success as to have gained for it the title of *divinum remedium*. The fact, however, appears to be, that it is merely a stimulant aromatic, analogous but inferior to Angelica, which has nearly superseded it in European practice. In this country, it is unknown as a remedy, and its vulgar name has been applied to another plant.

INDELIBLE INK. This is prepared by dissolving two drachms of nitrate of silver and a drachm of gum arabic in a fluidounce of distilled water, coloured with a little Indian ink. It is used for writing with a pen on linen and muslin. The place to be marked is prepared by being moistened with a solution of two ounces of crystallized carbonate of soda, and two drachms of gum Arabic in four fluidounces of water, and then dried. The alkaline solution serves to decompose the nitrate, and to protect the cloth from the action of the free nitric acid. At the end of twenty-four hours, the spot is to be washed.

INDIAN RED. A purplish-red pigment, brought from the island of Ormus in the Persian Gulf. It is a *red ochre*, and owes its colour to the red oxide of iron.

INDIGO. This well known and highly important dye-stuff, is obtained from various species of *Indigofera*, especially the *I. tinctoria*, *I. Anil*, and *I. argentea*; and is said to be afforded also by other plants, such as the *Wrightia tinctoria*, *Polygonum tinctorium*, *Galega tinctoria*, &c. In the process of preparing it, the plant is macerated in water; fermentation takes place; the liquor becomes of a greenish colour, and in due time is decanted; the colouring principle dissolved by the water absorbs oxygen from the air, and assumes a blue colour, becoming at the same time insoluble; a gradual precipitation takes place, favoured by the addition of lime-water or an alkaline solution; and finally, the precipitated matter, having been washed upon linen filters, is dried, shaped usually into cubical masses, and sent into market. Most of the indigo consumed in dyeing is brought from the East Indies, though considerable quantities are imported also from Guatemala and the northern coast of South America. It is of an intensely blue colour, but assumes a coppery or bronze hue when rubbed by a smooth hard body, as the nail. Heated to 550°, it emits a reddish-violet vapour, which condenses in minute crystals. It is insoluble in water or alcohol, but is readily dissolved by sulphuric acid, which, without destroying its blue colour, so far alters its nature as to render it freely soluble in water, and thus affords a convenient method of applying it to the purposes of dyeing. The solution in sulphuric acid is sometimes kept in the shops under the name of *sulphate of indigo*. According to Berzelius, indigo contains, among other ingredients, four distinct principles;—1, a substance resembling gluten; 2, a brown colouring substance; 3, a red colouring substance; and 4, a blue

colouring substance, which is the principle upon which its value as a material for dyeing depends, and which seldom constitutes so much as one-half of the indigo of commerce. This blue colouring matter is called *indigotin*. By deoxidizing agents it is deprived of its blue colour, which it recovers by exposure to the air, in consequence of the absorption of oxygen. Chlorine also destroys the blue colour.

Indigo has recently been introduced to the notice of the profession as a remedial agent. It has hitherto been chiefly employed by the German physicians, from whose statements our knowledge of its physiological action and therapeutical applications is derived. Though without odour and taste, it is said, in most individuals, to produce nausea and vomiting, frequently to operate upon the bowels, giving a bluish-black colour to the stools, to render the urine of a dark-violet or dark-green colour, without increasing its quantity, and sometimes to stimulate the secretory function of the uterus. From these statements it would appear to act as an irritant to the alimentary mucous membrane. The character of its general influence upon the system has not been well ascertained. In some instances, it is asserted to have been employed in very large doses without any obvious effect. The complaints in which it has been employed, with supposed advantage, are epilepsy, infantile convulsions, chorea, hysteria, and amenorrhœa. It is given, usually in connexion with some aromatic powder, in the dose of a scruple three times a day, which may be increased to a drachm or more; and from half an ounce to an ounce daily has been employed for months together without disadvantage. (See *Am. Jour. of Med. Sci.* xx. 487.)

IODIDE OF AMMONIUM. *Ammonii Iodidum. Hydriodate of Ammonia.* This salt is formed by saturating liquid hydriodic acid with caustic ammonia, and evaporating the solution. It forms a deliquescent saline mass, which crystallizes with difficulty in cubes. It is mentioned by Dr. Pennock as a good remedy in some cases of lepra and psoriasis, made up into an ointment. (*Amer. Journ. of Med. Sciences*, xv. 374.) The proportions employed are from a scruple to a drachm of the salt to an ounce of lard; the weaker preparation being used when the disease is recent, the stronger when it is chronic. The ointment was employed in frictions in the amount of half an ounce, morning and evening. As the iodide is decomposed by exposure to the air, the ointment should be kept in well stopped bottles.

IODIDE OF ARSENIC. *Arsenici Iodidum.* This compound may be formed by heating very gently a mixture of one part of finely powdered metallic arsenic with five of iodine. The product is then sublimed, to separate the iodide from the excess of arsenic. It is an orange-red, volatile substance, soluble in water. When in concentrated solution, it is decomposed by standing into arsenic and hydriodic acids. Iodide of arsenic has been used by Biett as an external application to corroding tubercular skin diseases. By Dr. A. T. Thomson it has been given internally with advantage in lepra, impetigo, and diseases resembling cancer. Dr. F. C. Crane reports a cure, by its use for nearly eight months, of what he considered cancer of the breast. The ointment used by Biett was composed of three grains of the iodide to an ounce of lard. The dose for internal exhibition is an eighth of a grain, gradually increased to a third, given in pill three times a day.

IODIDE OF BARIUM. *Barii Iodidum.* This compound may be formed by double decomposition, by adding carbonate of baryta to a boiling solution of iodide of iron. M. Henry, Jun., obtains it by decomposing a solution of sulphuret of barium (see page 874) by a concentrated alcoholic solution of iodine. Sulphur is precipitated, which is separated by filtration, and iodide of barium formed in solution, from which it is obtained in the solid state, by a rapid evaporation to dryness. It crystallizes in small, colourless needles, which deliquesce slightly, and are very soluble in water. The solution promptly undergoes decomposition by exposure to the air, carbonate of baryta being precipitated, and iodine set free, which colours the solution. It has been used with advantage by Jahn as an alterative, in scrofulous affections and morbid growths. Lugol employed it in scrofulous enlargements. The dose is the eighth of a grain three times a day, gradually increased to three grains. Biett applied it to scrofulous swellings in the form of ointment, made with four grains of the iodide to an ounce of lard.

IODIDE OF SILVER. *Argenti Iodidum.* This compound is formed by double decomposition, by adding a solution of iodide of potassium to one of nitrate of silver. It is a greenish-yellow powder, nearly insoluble in ammonia. It possesses the general medical properties of the preparations of silver, and, according to Dr. Charles Patterson, of Dublin, may be used without any danger of producing the discoloration of the skin which sometimes follows the use of the nitrate of silver. Dr. Patterson found it generally successful in curing the stomach affections of the Irish peasantry,

in the treatment of which nitrate of silver had been previously found useful. He gave it in the form of pill, in the dose of a fourth of a grain, mixed with an equal weight of nitrate of potassa, three times a day.

IODIDE OF STARCH. Dr. A. Buchanan, of Glasgow, proposes this compound as a means of administering iodine in large doses without causing irritation of the stomach. He prepares it by triturating twenty-four grains of iodine with a little water, adding gradually a drachm of very finely powdered starch, and continuing the trituration until the compound assumes a uniform blue colour. The iodide is then dried by a gentle heat, and kept in a well stopped bottle. The dose is a heaped teaspoonful, given in water gruel, three times a day, and afterwards increased to a table-spoonful. No nicety is necessary in apportioning the dose. In some cases Dr. Buchanan has given half ounce doses of the iodide three times a day, immediately increased to an ounce. Exhibited in this state of combination, iodine produces, according to this writer, little or no irritation of the alimentary canal, but is freely absorbed, as is proved by its detection in large quantity in the secretions. Dr. Buchanan conceives that, by means of the starch, the iodine is converted into hydriodic acid, and in this form of combination enters the circulation. He prefers the iodide of starch to any other preparation of iodine for obtaining the alternative apart from the irritant effects of this substance. See *Hydriodic acid*, page 1261. (*Amer. Journ. of Med. Sci.* xx. 213 and 217.)

IODIDE OF ZINC. *Zinci Iodidum.* This iodide may be formed by digesting an excess of zinc, in small pieces, with iodine diffused in water. Combination takes place, and by evaporation, a deliquescent, very soluble saline mass is obtained, having a metallic, styptic taste, resembling that of sulphate of zinc. It may also be obtained by heating in a matrass a mixture of 20 parts of zinc and 170 of iodine, and subliming into a vial. When thus prepared, it is in the form of white needles. It is very liable to undergo spontaneous decomposition.

Iodide of zinc is tonic and astringent. We have not met with any notice of its internal exhibition; but Dr. A. T. Thomson proposes a *syrup* of it, to protect it from change, made on the same plan as the syrup of iodide of iron. (See page 965.) Dr. J. J. Ross, of Scotland, employed a solution of iodide of zinc, containing from 10 to 30 grains to the fluidounce of water, with great advantage in enlarged tonsils, applied by means of a piece of sponge tied to a quill. After the use of the solution for some time, he applied the iodide, rendered liquid by deliquescence, by means of a camel's hair brush. A solution containing one or two grains to the fluidounce of water, has been used as an astringent injection in gonorrhœa. An ointment, made of a drachm of the iodide, rubbed up with an ounce of lard, has been proposed by Dr. Ure as a substitute for iodide of potassium in the treatment of tumours, applied in the quantity of a drachm twice a day.

IDO-HYDRARGYRATE OF POTASSIUM. It has been found by chemists that different iodides will unite together in definite proportions, forming compounds which are called by Berzelius double iodides. Bonsdorff of Finland, and Dr. Hare of this city, with greater reason, have viewed these combinations as a peculiar kind of salts, in which one of the iodides performs the part of an acid, the other of a base. The substance, the name of which is placed at the head of this article, is one of these compounds, and was presented to the notice of the profession, as a new remedy of remarkable powers, in February, 1834, by Dr. William Channing of New York. (*Amer. Journ. of Med. Sci.* xiii. 388.) It consists of the biniodide of mercury acting as an acid, united with the iodide of potassium as a base. But as these two iodides combine in at least two proportions, it is necessary to indicate the particular combination employed by Dr. Channing in his therapeutic experiments.

In a difficult case of pectoral disease, in which the ordinary remedies had failed, Dr. Channing determined to make trial of one of the iodides of mercury. He selected the biniodide; and in order to have it in the liquid form, it being insoluble in water, he dissolved it in a solution of iodide of potassium. He was struck with the chemical changes which the compound solution underwent; and on pursuing his observations he found that the two iodides really united by the intervention of the water; for by the assistance of an operative chemist, he was enabled by evaporation to obtain them in union in the form of straw-coloured, needleform, deliquescent crystals. He next found, upon consulting the European authorities, that Bonsdorff, who had taken the lead in investigating similar compounds, had discovered the same salt in 1826.

Dr. Channing analyzed the salt with which he experimented, and found that it consisted of one eq. of biniodide of mercury, and two of iodide of potassium. This he

determined by ascertaining that an aqueous solution of a little more than eight grains of iodide of potassium would dissolve, and combine with, eleven grains of biniodide of mercury, without being liable to decomposition when largely diluted with water.

The combination here indicated corresponds with one of the double iodides of mercury and potassium, as described by Thenard. (*Traité de Chimie*, 6ème Ed. iii. 493.) The other is represented by this author as consisting of a single eq. of each iodide. When copiously diluted with water, every two eqs. of this iodide let fall one eq. of the mercurial iodide; thus evidently converting the salt into the medicinal double iodide. The same decomposition by the use of abundance of water is noticed by Dr. Channing. For remarks on these double iodides see a paper by Mr. Ambrose Smith, *Am. Journ. of Pharm.* xii. 265.

Dr. Channing attributes to this preparation the effects of diffusing excitement, and equalizing the circulation. In the different cases in which he tried it, he thought he saw evidence of its favourable influence on the lungs, in allaying cough and improving expectoration; on the alimentary canal, in restoring the healthy secretions; on the kidneys, in reviving their activity; on the skin and cellular tissue, in cicatrizing superficial ulcerations; and on the absorbent and exhalent systems, in causing the disappearance of effused fluid. The principal diseases in which he found it useful were chronic bronchitis, hooping-cough, tonsillitis, chronic gastro-enteritis, dyspepsia, ascites, anasarca, amenorrhœa, leucorrhœa, eruptions, and scrofula. In some cases of phthisis, it mitigated the symptoms and appeared to prolong life. Dr. Hildreth, of Ohio, has tried this preparation, and reports favourably of its effects in ordinary dyspepsia unattended by organic disease, enlargement of the spleen, amenorrhœa, dysmenorrhœa, leucorrhœa, scrofulous affections, ascites, and general dropsy. (*Am. Journ. Med. Sci.* xxvi. 312.)

The average dose of the remedy may be stated at the twelfth of a grain three times a day; but in peculiar constitutions, not more than the forty-eighth, the ninety-sixth, or even the two-hundredth of a grain daily can be borne. For the convenience of physicians who may wish to make trial of the remedy, we give the following formula, deduced from the statements in Dr. Channing's paper.—Take of iodide of potassium three and a half grains; biniodide of mercury (red iodide), four and a half grains; distilled water a fluidounce. Dissolve first the iodide of potassium and then the biniodide of mercury in the water. The compound salt in this solution may be assumed to amount to eight grains, though there is a small excess of the iodide of potassium. Of the solution, from two to five drops, containing from the thirtieth to the twelfth of a grain, may be given three times a day.

IONIDIUM MARCUCCI. This name has been conferred by Dr. Bancroft upon a South American plant, supposed to be the source of a medicine used with great asserted advantage in Maracaybo and elsewhere, in some of the horrible cutaneous affections to which the inhabitants of the tropical regions of this continent are subject. A specimen, however, received from Dr. Bancroft was found by Sir W. Hooker to be identical with the *Ionidium parviflorum* of Ventinat. The medicine is called by the Indians *cuichunchulli*, and grows in the neighbourhood of Riobamba, a small town at the foot of the great mountain of Chimborazo. It is said to be diaphoretic, diuretic, occasionally sialagogue, and in large doses emetic and cathartic. The root is the part used. It is highly probable that other vegetable emeto-cathartics, having the same property of stimulating the secretions, would be found equally effectual. For an account of what is known in relation to this medicine the reader is referred to a paper by Dr. Bancroft, republished in the American Journal of Pharmacy, vol. iii. p. 125.

ISATIS TINCTORIA. *Wood. Pastel.* A biennial plant, indigenous in Europe, where it is also cultivated. The leaves have a fugitive pungent odour, and an acrid very durable taste, and have been used in scorbutic affections, jaundice, and other complaints; but the plant is valuable only as a source of a blue dye-stuff, called *woad*, which has been long employed in Europe, though at present nearly superseded by indigo. The leaves are prepared by grinding them to a paste, which is made into balls, placed in heaps, and allowed to ferment. When the fermentation is at an end, the mass falls into a coarse powder, which is the dye-stuff in question.

KALMIA LATIFOLIA. *Laurel. Mountain-laurel. Broad-leaved-laurel. Calico-bush.* This well known evergreen inhabits all sections of the United States, but is particularly abundant on the sides of hills and mountains, which it adorns in summer with its elegant flowers. It is from three to ten feet in height. The leaves are endowed with poisonous, narcotic properties, and have been used in medicine. They

are said to prove fatal to sheep and some other animals, but are eaten with impunity by deer, goats, and partridges. Dr. Barton states in his "Collections," that the Indians sometimes use a decoction of the leaves to destroy themselves. It is said that death has been occasioned by eating the flesh of partridges and pheasants which have fed upon them during winter. Dr. Shoemaker published, in the North American Medical and Surgical Journal, two cases of poisoning which resulted from eating a pheasant, in the craw of which laurel leaves were found. The symptoms were nausea, temporary blindness, pain in the head, difficult breathing, pallid countenance, cold extremities, and very feeble pulse, which in one case was for some time absent at the wrist, in the other beat only forty strokes in the minute. In both instances relief was afforded by vomiting produced by a tablespoonful of flour of mustard mixed with warm water.

Dr. Barton was informed that the powdered leaves were employed by an empiric with success in certain states of fever; and Dr. Thomas, in an inaugural dissertation, published at Philadelphia, A. D. 1802, states that a case of diarrhoea, of eight weeks duration, was cured by a decoction made by boiling an ounce of the leaves in eight ounces of water down to four ounces. Thirty drops were given six times a day; but this quantity produced vertigo, and the dose was afterwards repeated only four times daily. The leaves are said also to have been used advantageously in syphilis. Externally applied, in the shape of ointment or decoction, they have been found useful in tinea capitis, psora, herpes, and other cutaneous affections; but some caution is necessary in their application, as, according to Dr. Barton, nervous symptoms have resulted from the external use of the decoction. Dr. Bigelow has seen the recently powdered leaves given in doses of from ten to twenty grains, without perceptible effect.

It is probable that the other species of *Kalmia*—as the *K. angustifolia*, or *sheep-laurel*, and the *K. glauca*, or *swamp-laurel*, have properties identical with those of the *K. latifolia*.

LABDANUM. *Ladanum*. A resinous substance obtained from various species of *Cistus*, especially the *C. Creticus*, *C. ladaniferus*, and *C. laurifolius*, small evergreen shrubs, inhabiting the islands of the Grecian Archipelago, and the different countries bordering on the Mediterranean. Upon the leaves and branches of these shrubs a juice exudes, which is collected by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant. The juice adheres to the pieces of leather, and is afterwards separated. It is said that labdanum was formerly collected by combing the beards of goats which had been browsing upon the leaves of the *cistus*. It comes chiefly from the Grecian islands. Two varieties exist in commerce. The *purest labdanum* is in masses of various sizes, sometimes weighing several pounds, enclosed in bladders, of a dark-red almost black colour externally, grayish internally when first broken, of the consistence of a plaster, softening in the hand and becoming adhesive, of an agreeable balsamic odour similar to that of amber, and of a bitter, balsamic, somewhat acrid taste. It is very inflammable, burning with a clear flame. On exposure it becomes dry, porous, and brittle. Little of this variety is found in the markets. *Common labdanum* is in pieces of a contorted or spiral form, light, porous, blackish-gray, hard and brittle, not softening between the fingers, similar in odour and taste to the preceding variety, but less inflammable, and mixed with much sand and other earthy matter, which are obvious to the sight. Guibourt found in 100 parts of the labdanum in masses, 86 parts of resin with a little volatile oil, 7 parts of wax, 1 of watery extract, and 6 of earthy substances and hair. In the contorted variety, Pelletier found 20 per cent. of resin, 3.6 of gum with malate of lime, 0.6 of malic acid, 1.9 of wax, 1.9 of volatile oil including loss, and 72 of ferruginous sand.

Labdanum is a stimulant expectorant, and was formerly given in catarrhal and dysenteric affections. At present it is employed only as an ingredient in plasters, and seldom even for that purpose in the United States. It is sometimes used in fumigation.

LAC. A resinous substance obtained from several trees growing in the East Indies, particularly from the *Croton lacciferum*, and two species of *Ficus*, the *F. religiosa* and *F. Indica*. It is found in the form of a crust surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect belonging to the genus *Coccus*, and denominated *C. Lacca*. By some it is thought to be an exudation from the bodies of the insects themselves, which collect in great numbers upon the twigs, and are embedded in the concretion juice, through which the young insects eat a passage and escape. Several

varieties of lac are known in commerce. The most common are *stick lac*, *seed lac*, and *shell lac*.

Stick lac is the resin as taken from the tree, still encrusting the small twigs around which it originally concreted. It is of a deep reddish-brown colour, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle; and when broken it exhibits many oblong cells, often containing the dead insect. When chewed it colours the saliva beautifully red, and when burnt, diffuses a strong agreeable odour. It is in great measure soluble in alcohol. Little of this variety is imported.

Seed lac consists of minute irregular fragments broken from the twigs, and partially exhausted by water. It is of a light or dark brown colour, inclining to red or yellow, feebly shining, almost tasteless, and capable of imparting to water less colour than the stick lac, sometimes scarcely colouring it at all. It is occasionally mixed with small fragments of the twigs.

Shell lac is prepared by melting the *stick* or *seed lac* previously deprived of its soluble colouring matter, straining it, and pouring it upon a flat smooth surface to harden. It is in thin fragments of various sizes, from half a line to a line thick, often somewhat curved, of a lighter or darker brown colour, inclining more or less to red or yellow, shining, more or less transparent, hard and brittle, inodorous and insipid, insoluble in water, but easily and almost entirely soluble in alcohol, especially with the aid of heat.

A variety of lac is mentioned by writers, in the form of cakes, called *cake* or *lump lac* (*lacca in placentis*); but this is at present rare in commerce.

According to John, lac consists of resin, colouring matter, a peculiar principle insoluble in alcohol, ether, or water, called *laccin*, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and ether. The laccin is nearly or quite wanting in the *shell lac*, which also contains scarcely any of the colouring principle. Mr. Hatchet found in *stick lac* 68 per cent. of resin and 10 of colouring matter; in *seed lac* 88.5 per cent. of resin and 2.5 of colouring matter; in *shell lac* 90.9 per cent. of resin and 0.5 of colouring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters.

Lac in its crude state is slightly astringent, and was formerly used in medicine. At present it is not employed. Shell lac is wholly inert. Stick lac and seed lac are used on account of the colouring principle which they contain. Shell lac, as well as the other varieties deprived of their colouring matter, is applied to numerous purposes in the arts. It is the chief constituent of sealing wax. The best *red sealing wax* is made by melting together, with a very gentle heat, 48 parts of shell lac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common rosin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. The best *black sealing wax* consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone black; the best *yellow sealing wax*, of 60 parts of lac, 12 of turpentine, and 24 of chromate of lead. (Berzelius.) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and earthenware.

LACTATE OF IRON. *Ferri Lactas. Lactate of Protoxide of Iron.* MM. Gélis and Conté introduced this preparation to the notice of the profession. It being admitted by physiologists, except Liebig, that the lactic acid is the principal acid present in the gastric juice, they concluded that the ordinary ferruginous preparations, when efficacious, are dissolved by this acid in the stomach, and were led to suppose that the lactate of iron, ready formed, might prove a valuable remedy. Their anticipations, thus far, have been realized; for several French physicians of note, among whom are MM. Fouquier, Bally, and Bouillaud, the committee appointed on their memoir by the French Academy of Medicine, have reported favourably in relation to its therapeutic powers.

M. Louradour recommends the following process for obtaining lactate of iron. Ferment whey by keeping it at a temperature between 70° and 80°, whereby it becomes charged with a considerable quantity of lactic acid. Evaporate the liquor to a third of its bulk, decant and filter, and then saturate with milk of lime. This converts the lactic acid into lactate of lime, which remains in solution, and throws down a precipitate, consisting principally of phosphate of lime. The liquor is again filtered, and precipitated by oxalic acid, which throws down the lime as oxalate of lime, and sets free the lactic acid. By a new filtration a solution of lactic acid is obtained, con-

taining lactic acid and certain salts, but pure enough for conversion into lactate of iron. For this purpose iron filings are digested with it on a sand-bath at a gentle heat. At the end of six or seven hours, the liquor is made to boil; after which it is filtered, concentrated, and allowed to cool and crystallize. The lactic and foreign salts remain in the mother-water. The crystals are drained in a funnel, washed with alcohol, dried rapidly, and then transferred to a bottle which must be well stopped. The salt, thus obtained, is in very white crystalline plates, undergoing little change in the air. When in the form of a yellowish or greenish-white powder it is impure. It is but sparingly soluble in water, requiring forty parts of boiling water to dissolve it. It has an acid reaction, and possesses a mild ferruginous taste. The aqueous solution quickly becomes yellow, in consequence of the iron passing to a higher state of oxidation. M. Louradour has observed several samples of this lactate, variously adulterated; as by effloresced sulphate of iron, starch, and sugar of milk; the sophistication being concealed by the salt being sold in powder. These impurities may be detected by appropriate reagents; but M. Louradour recommends, as a simpler way of avoiding them, the rejection of the salt when not in crystalline plates.

Medical Properties. Lactate of iron has the general medical properties of the ferruginous preparations. It has a marked effect in increasing the appetite. The disease in which it was principally tried in Paris, was chlorosis, with or without amenorrhœa, and in this disease, Andral, Fouquier, Bouillaud and others, obtained very favourable results. The dose is one or two grains, repeated at intervals and gradually increased. As much as 12 or even 20 grains may be given in the course of the day. It may be administered in lozenge, pill, or syrup. The *lozenge* may be made of one grain of the lactate to twelve of sugar; and the *pill*, of one grain of the salt, made up with an equal weight of some inert powder free from astringent matter, and sufficient honey. The following is the formula for a *syrup* proposed by M. Cap, expressed in the nearest weights and measures used in this country. Take of lactate of iron *a drachm*; white sugar *twelve ounces and a half*; boiling distilled water *six fluidounces and a half*. Rub the salt to powder with four times its weight of the sugar; and dissolve the mixture quickly in the boiling water. Pour the solution into a matrass placed on a sand-bath, and add to it the rest of the sugar in small pieces. When the sugar is dissolved, filter the syrup, and, as soon as it is cold, transfer it to bottles which must be well stopped. This syrup has a very light amber colour and contains about four grains of the salt to the fluidounce. The dose is from two to four fluidrachms. Bread, called *chalybeate bread*, containing the lactate of iron, in the proportion of about a grain to the ounce, has been used, with advantage, by chlorotic patients in one of the hospitals of Paris. The bread is not injured in taste or quality.

LACTIC ACID. *Acidum Lacticum.* This acid was discovered by Scheele. It is interesting as having been found in a number of the secretions, particularly the urine. It is a product of the viscous fermentation of rice-water, and of the juices of the beet, turnip, and carrot. It may be conveniently obtained from the solution of impure lactic acid, mentioned in the last article, by concentrating it to a syrupy consistence, and treating it with alcohol, which dissolves the acid and precipitates the lactic and foreign salts. The solution is filtered, and the lactic acid is obtained pure by distilling off the alcohol. It is a colourless syrupy liquid, having a very sour taste, and the sp. gr. 1.215. When heated to 480°, the greater part of it is converted into a new body called concrete lactic acid. It coagulates albumen, and dissolves a large quantity of freshly precipitated phosphate of lime, a property which, doubtless, renders it of importance in the animal economy. The hydrated acid consists of six eqs. of carbon, five of hydrogen, and five of oxygen, plus one eq. of water.

Lactic acid was proposed by Magendie on theoretical grounds as a remedy in certain forms of dyspepsia, and for the removal of phosphatic deposits in the urine. It is most conveniently given in solution sweetened with sugar, formed like lemonade. From one to three drachms may be taken in the course of the day.

LAKES. These are compounds of vegetable or animal colouring principles with alumina or metallic oxides, and are usually obtained by adding alum, or perchloride of tin, to the solution of the colouring matter in water, and precipitating by means of an alkali. The alumina or oxide of tin unites with the colouring matter at the moment of separation, and forms an insoluble compound. Lakes are obtained in this way from cochineal, madder, Brazil wood, seed lac, French berries, &c. They are used in painting.

LEDUM PALUSTRE. *Marsh Tea. Rosmarinus sylvestris.* A small evergreen shrub, growing in swamps and other wet places, in the northern parts of Europe, Asia, and America, and in the mountainous regions of more southern latitudes. The

leaves have a balsamic odour, and an aromatic, camphorous, bitter taste; and contain, among other ingredients, volatile oil and tannin. They are thought to possess narcotic properties, and have been employed in exanthematous diseases to allay febrile irritation, in whooping-cough, in dysentery, and in various cutaneous affections, particularly leprosy and scabies. In complaints of the skin, they are used both internally and externally, in the form of decoction. When placed among clothes, they are said to prevent the attacks of moths. In Germany, they are sometimes substituted for hops in the preparation of beer. The *Ledum latifolium*, or *Labrador tea*, which is a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern parts of the United States. The leaves, as in the former species, have an agreeable odour and taste, and are esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war of independence.

LEPTANDRA VIRGINICA. Nuttall. *Veronica Virginica*, Linn. *Culver's Physic*. This is an indigenous perennial plant, with an herbaceous stem three or four feet high, furnished with leaves in whorls, and terminating in a long spike of white flowers. A variety was seen by Pursh with purple flowers. This was described and figured as a distinct species by Rafinesque, under the title of *L. purpurea*. The plant grows throughout the United States, affecting particularly calcareous hills and sunny exposures, and flowering in August. The root, which is the part used, is bitter and nauseous, and yields its active properties to boiling water. When recent it is said to act violently as a cathartic, and sometimes as an emetic. In the dried state it is more uncertain. The dose of the powder is from twenty grains to a drachm. It was formerly among the officinals of the U. S. Pharmacopœia, but has been omitted in the last edition.

LIATRIS SPICATA. *Gay-feather*. *Button Snakeroot*. An indigenous perennial plant, growing in natural meadows and moist grounds throughout the Middle and Southern States. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple, compound flowers, which appear in August. The root is said by Schoepf to have a terebinthinate odour, and a warm, bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful in gonorrhœa and sorethroat, being employed internally in the shape of decoction in the former complaint, and as a gargle in the latter. Pursh informs us, that the *L. scariosa* and *L. squarrosa*, are known in Virginia, Kentucky, and the Carolinas, by the name of *Rattlesnake's master*; and that their roots are employed to cure the bite of the rattlesnake, being bruised and applied directly to the wound, while their decoction in milk is taken internally. According to Dr. William Barton, all the tuberous-rooted species of *Liatris* are active plants, and appear to be diuretic.

LIGUSTICUM LEVISTICUM. *Lovage*. An umbelliferous plant, growing wild in the South of Europe, and cultivated in gardens. The whole plant has a strong, sweetish, aromatic odour, and a warm pungent taste. When wounded it emits a yellow opaque juice, which concretes into a brownish resinous substance not unlike opopanax. The roots, stem, leaves, and seeds have all been employed; but the last have the aromatic properties of the plant in the highest degree. They are small, ovate-oblong, somewhat flattened, curved, strongly ribbed, and of a yellowish-brown colour. The medical properties of lovage are closely analogous to those of angelica. It is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion.

LIGSTRUM VULGARE. *Privet*. A shrub from four to ten feet in height, growing wild both in Europe and the United States, usually in hedges and by the roadside. The leaves, which have an astringent, bitter taste, and the flowers, which are small, snow-white, and of an agreeable odour, have been used, in the form of decoction, in sorethroat, and aphthous and scorbutic ulceration of the mouth. The berries are black, have a sweetish, bitter taste, and are said to possess purgative properties, and to colour the urine brown. They are sometimes used for dyeing. The bark was analyzed by M. G. Potex, who found a peculiar substance which he denominated *ligustrin*, besides mannite, sugar, muco-saccharine matter, starch, chlorophylle, bitter extractive, bitter resin, tannin, albumen, and salts. (*Am. Journ. of Pharm.* xii. 347.)

LILIUM CANDIDUM. *Common White Lily*. This well known plant is a native of Syria and Asia Minor, but has been long cultivated in gardens. The bulb, which consists of imbricated fleshy scales, is without odour, but has a peculiar, disagreeable, somewhat bitter and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle, which is dissipated or destroyed by roasting or boil-

ing. In the recent state it is said to have been employed with advantage in dropsy. Boiled with water or milk it forms a good emollient cataplasm, more used in popular than in regular practice. The flowers have an agreeable odour, which they impart to oil or lard; and an ointment or liniment is sometimes prepared from them, and used as a soothing application in external inflammations.

LIQUIDAMBAR STYRACIFLUA. *Sweet-gum.* An indigenous tree, growing in different parts of the United States from New England to Louisiana, and flourishing also in Mexico, where, as well as in our Southern States, it sometimes attains a great magnitude. In warm latitudes a balsamic juice flows from its trunk when wounded. This has attracted some attention in Europe, where it is known by the name of *liquidamber*, or *copalm balsam*, and is sometimes, though erroneously, called *liquid storax*. It is not afforded by the trees which grow in the Middle States, and is obtained from Mexico and Louisiana. It is a liquid of the consistence of thin honey, more or less transparent, of a yellowish colour, of a peculiar, agreeable, balsamic odour, and a bitter, warm, and acrid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker colour. According to M. Bonastre, it contains a colourless volatile oil, a semi-concrete substance which rises in distillation and is separated from the water by ether, a minute proportion of benzoic acid, a yellow colouring substance, an oleo-resin, and a peculiar principle, insoluble in water and cold alcohol, for which M. Bonastre proposes the name of *styracine*. The proportion of benzoic acid is greatly increased by time. Mr. Hodgson obtained from a specimen which he examined 4.2 per cent. (*Journ. of the Phil. Col. of Pharm.* vi. 190.)

Another product is said to be obtained from the same tree by boiling the young branches in water, and skimming off the fluid which rises to the surface. It is of a thicker consistence and darker colour than the preceding, is nearly opaque, and abounds in impurities. This also has been confounded with liquid storax, which it resembles in properties, though derived from a different source.

Liquidamber may be employed for the same purpose as storax, but is very seldom used, and is almost unknown in the shops of the United States.

LITHOSPERMUM OFFICINALE. *Gromwell. Milium Solis.* A European perennial, the seeds of which are ovate, of a grayish-white or pearl colour, shining, rather larger than millet seeds, and of a stony hardness, from which the generic name of the plant originated. From an opinion formerly prevalent, that nature indicated remedies adapted to certain diseases by some resemblance between the remedy and the character of the complaint or of the part affected, the seeds of this plant were applied to the treatment of calculous disorders; and they retained their ground in the estimation of physicians as a diuretic, useful in complaints of the urinary passages, long after the fanciful notion in which their use originated had been abandoned. But they are at present considered nearly inert, and are not employed.

LYCOPodium CLAVATUM. *Club-moss.* The capsules of this moss, and of others belonging to the same genus, contain a fine dust or powder, which is collected in Switzerland and Germany, and used in the shops of Europe under the name of *lycopodium*, or *vegetable sulphur*. This powder is considered by some as the pollen of the plant, by others as the seed. It is extremely fine, very light, of a delicate yellow colour, inodorous and tasteless, and exceedingly inflammable, so much so that it takes fire like gunpowder when thrown upon a burning body. It is said to be often adulterated with the pollen of the pines and firs, and sometimes with talc and starch. In medicine, it is used as an absorbent application to excoriated surfaces, especially those which occur in the folds of the skin in infants. In pharmacy, it answers the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. It is not much used in this country. The moss itself, from which the powder is derived, has been esteemed diuretic, antispasmodic, &c.; and has been employed, in the form of decoction, in rheumatism, epilepsy, and complaints of the lungs and kidneys; but it has fallen into discredit.

MANDRAGORA OFFICINALIS. *Atropa Mandragora, Linn. Mandrake. Mandragora.* A perennial European plant, with spindle-shaped root, which is often forked beneath, and is, therefore, compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, and was used as an amulet to promote fecundity, &c.; and the superstition is still cherished by the vulgar in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. It was much used by the ancients, with a view to its narcotic effects; and the root has been recommended

by some eminent modern physicians, as an external application to scrofulous, scirrhous, and syphilitic tumours. It is unknown as a remedy in the United States.

MEDEOLA VIRGINICA. *Gyromia Virginica*, Nuttall. *Indian Cucumber*. An indigenous perennial herb, growing in all parts of the United States. The root, which in shape and flavour bears a strong resemblance to a small cucumber, is said by Pursh to be eaten by the Indians. According to the late Professor Barton, it has been thought useful in dropsies, and probably possesses diuretic properties. It is figured and described by Dr. William Barton in his *Medical Botany*.

MELILOTUS OFFICINALIS. *Melilot*. An annual or biennial plant, indigenous in Europe, and growing also in this country. We have two varieties, one with yellow, the other with white flowers, which are considered by some as distinct species. The plant when in flower has a peculiar sweet odour, which, by drying, becomes stronger and more agreeable, somewhat like that of the tonka bean. Indeed, according to M. Guillemette, the odorous principle of the two substances is identical. (*Journ. de Pharm.* xxi. 172.) The taste of melilot is slightly bitterish. It has little medical power, and, though formerly recommended in various diseases, is at present not employed internally. As a local application, it is used, in the form of decoction or cataplasm, in moderate inflammations, though probably with little other advantage than such as results from the combination of warmth and moisture.

MESEMBRYANTHEMUM CRYSTALLINUM. *Ice-plant*. A biennial plant, growing spontaneously in the South of Europe, and cultivated as a curiosity in colder countries, by the aid of artificial warmth. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. The herb is without smell, and has a saline somewhat nauseous taste. It is considered demulcent and diuretic, and has been highly lauded as a remedy in various complaints, especially in those affecting the mucous membrane of the lungs and urinary passages. It has also been used in dropsy. The expressed juice is the form in which the remedy has been generally employed.

MOMORDICA BALSAMINA. *Balsam apple*. *Balsamina*. An annual climbing plant, a native of the East Indies, but cultivated in our gardens for the sake of the fruit. This is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or orange-yellow colour, easily falling when touched, and spontaneously separating into several pieces. It was formerly highly esteemed as a vulnerary, and is still in use among the common people. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to chapped hands, burns, old sores, piles, prolapsus ani, &c.; and the fruit itself is sometimes mashed and used in the form of poultice. According to M. Descourtitz, it is poisonous when taken internally, having proved fatal to a dog in the quantity of two or three drachms; and an extract prepared from it is said to be useful in dropsy, in the dose of from six to fifteen grains.

MONESIA. Under this name a vegetable extract from South America was, a few years since, introduced to the notice of the medical profession in France by M. Bernard Derosne, and for a time attracted much attention. It was obtained from an individual who had long resided in South America, and who, having observed the beneficial effects of the medicine in the bowel affections of that country, was desirous of having its properties investigated in Europe. The information, however, was not given, from what part of the continent it was derived, nor by what plant afforded; and a mystery hung over its origin, which, so far as we know, has not yet been cleared up. It was said to have been prepared from a bark, specimens of which were received by M. Derosne, and which was conjectured by him to belong to a tree of the genus *Chrysophyllum*; but nothing certain is known upon the subject. An extract made from this bark was found to be identical with that imported.

The bark is in pieces, some of which are three or four lines thick, is very compact and heavy, of a deep-brown or chocolate colour, contrasting strongly with the grayish colour of the epidermis when this remains, and of a smooth fracture. The extract was received from S. America in cakes weighing rather more than a pound, from three quarters of an inch to an inch in thickness, of a dark-brown almost black colour, very brittle, of a fracture neither very dull nor very shining, and of a taste at first sweet, then astringent, and ultimately acrid, the acrimony being very persistent, and especially felt in the fauces. It is entirely soluble in water. The bark was analyzed by MM. Derosne, Henry, and Paven, and was found to contain in 100 parts, 1·2 of stearin, chlorophylle, and wax, 1·4 of glycyrrhizin, 4·7 of an acrid principle analogous to saponin, called *monesin*, 7·5 of tannic acid, 9·2 of a red colouring substance, 1·3 of malic acid and malate of lime, 3·0 of various salts, including

oxides of iron and manganese and silica, and 71·7 of pectic acid or pectin and lignin including loss, besides traces of an aromatic principle and of gum. *Monesin* was obtained by treating the bark or extract with alcohol, adding to the tincture an excess of hydrate of lime in fine powder, filtering, evaporating the clear liquor to dryness, treating the residue with water and animal charcoal, filtering, and again evaporating to dryness. Thus procured it was in transparent yellowish scales, which were easily pulverized, forming a white powder. It was readily dissolved by alcohol and water, to the latter of which it gave the property of frothing; but was insoluble in ether. It could not be made to crystallize. It had no power to saturate the acids, was without odour, but had a slightly bitterish taste followed by a very decided and permanent acrimony in the posterior mouth and fauces. (*Journ. de Pharm.* Janvier, 1841.) *Monesia* owes its activity probably to this principle and to tannic acid.

The effects of this medicine upon the system appear to be those of a moderate stomachic excitant, a general alterative, and a feeble astringent. According to M. St. Ange, in moderate doses it increases the appetite and invigorates digestion; in over doses, produces heat in the epigastrium with obstinate constipation and tenesmus. (*Med. Examin.* iii. 207, from *Gazette Médicale*.) It has been used internally with asserted advantage in diarrhœa, hæmoptysis, menorrhagia, scrofula, scurvy, the chronic catarrh of old people, and dyspepsia. As a local remedy it has been found useful in leucorrhœa, ulcerations of the mouth and fauces, spongy and scorbutic gums, carious teeth, and obstinate scrofulous and otherwise unhealthy ulcers upon the surface. The extract may be given in pill or powder, in aqueous solution, in tincture, or in syrup. The dose of it is from two to ten grains repeated every hour, two, or three hours, or less frequently. From ten grains to a drachm may be given daily. In scrofulous affections it must be given in large quantities, and persevered in for several weeks, in order to obtain its curative effects. *Monesia* is applied to ulcers either by being sprinkled in powder upon the surface, or in the form of ointment made with one part of the extract and seven parts of simple ointment. *Monesin*, or the acrid principle, has been given internally in the dose of about half a grain, and has also been applied to ulcers.

MURIATIC ETHER. *Æther Muriaticus.* *Muriate of Etherine.* *Chloride of Ethale.* This ether was discovered by Rouelle, but first obtained in sufficient quantities to permit the examination of its properties by Basse. It may be procured by several processes, but the following is the best.—Distil a mixture of equal measures of concentrated muriatic acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between 70° and 80°, and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ether which comes over into the first bottle, is mixed with alcohol and acid, which are retained by the water, while the pure ether passes forward, and is condensed in the refrigerated bottle. This ether must be kept in strong bottles, well-secured with ground stoppers covered with leather. Before being opened, the bottle should be cooled down to the freezing point.

Muriatic ether is colourless, has a strong, slightly saccharine, alliaceous taste, and a penetrating, ethereal, alliaceous smell. Its sp. gr. at the temperature of 41° is 0·774. It is extremely volatile, entering into ebullition at 54°, so that in summer it may be collected in the gaseous state, in bell-glasses over water. Its density in the state of vapour is 2·22. When kindled as issuing from a fine orifice, it burns with an emerald-green flame without smoke, diffusing a strong odour of muriatic acid; but when set on fire in quantities, it burns with a greenish-yellow smoky flame. Water dissolves one-fiftieth of its weight of this ether, and acquires a sweetish, ethereal taste, and alcohol unites with it in all proportions. These solutions are not precipitated by nitrate of silver, showing that the muriatic acid present is in a peculiar state of combination. Like sulphuric and nitric ether, it dissolves sulphur and phosphorus, the fat and volatile oils, and many other substances. It consists of one equiv. of muriatic acid 36·42, and one of etherine 28·48 = 64·9; or in volumes, of two volumes of the acid, and one volume of the vapour of etherine, condensed into two volumes.

Muriatic ether, like the other substances of this class, is a diffusible stimulant, but owing to its extreme volatility, cannot be kept in the shops. It may, however, be preserved in a cool cellar, the temperature of which does not rise above 45° or 50°, being well secured in bottles, which should be placed reversed. When used in medicine, it is generally mixed with an equal bulk of alcohol, when it is called *alcoholic muriatic*

ether. The dose is from five to thirty drops, given in sweetened water, or other convenient vehicle.

MUSHROOMS. *Fungi.* This extensive family of cryptogamous plants is interesting to the physician, from the consideration, that, while some of them are very largely consumed as food in different parts of the world, others are deleterious in their nature, and capable, when eaten, of producing poisonous effects. Their substance is made up of a cellular tissue, which is usually of that soft consistence denominated fungous, but is sometimes corky, ligneous, or even gelatinous. Many of them have an agreeable odour and taste, while others are unpleasant or offensive both to the nostrils and palate. According to Braconnot, most of them contain, among other substances, a peculiar principle denominated *fungin*, a peculiar acid called *fungic acid* usually combined with potassa, and a peculiar saccharine matter less sweet than the other varieties of sugar, less soluble in alcohol and water than that of the cane, and distinguished by some writers as the *sugar of mushrooms*. *Fungin* constitutes the basis of these vegetables, and is the principle upon which their nutritive properties chiefly depend. It is the fleshy substance which remains when they are treated with boiling water holding a little alkali in solution. It is whitish, soft, and insipid; inflammable; insoluble in water, alcohol, ether, weak sulphuric acid, and weak solutions of potassa and soda; soluble in heated muriatic acid; decomposed by nitric acid, and by concentrated alkaline solutions; and converted by destructive distillation into substances resembling those which result from the distillation of animal matters.

It is highly important for those who employ mushrooms as food, to be able to distinguish those which are wholesome from the poisonous. The following general rules are given by M. Richard in the *Dictionnaire des Drogues*. Those should be rejected which have a narcotic or fetid odour, or an acrid, bitter, or very acid taste; which occasion a sense of constriction in the throat when swallowed; which are very soft, liquefying, changing colour, and assuming a bluish tint upon being bruised; which exude a milky, acrid, and styptic juice; which grow in very moist places, and upon putrefying substances; in fine, all such as have a coriaceous, ligneous, or corky consistence. The last, however, are injurious in consequence rather of their indigestible than of their poisonous nature. Even mushrooms which are usually edible, may prove poisonous, if collected too late, or in places which are too moist. It is said, moreover, that the poisonous species sometimes become innocent when they grow under favourable circumstances; and that the most noxious may be rendered edible by boiling them in water acidulated with vinegar. Immense quantities of mushrooms are eaten in France, Germany, Italy, and other parts of continental Europe; and it is asserted that they constitute the chief food of the people in certain provinces.

The symptoms produced by the poisonous mushrooms are anxiety, nausea, faintness, vomiting, and, if they are not rejected from the stomach, somnolence, stupor, small and intermittent pulse, tension of the abdomen, cold extremities, livid skin, and death in thirty-six or forty-eight hours. Sometimes violent pains in the stomach and bowels are experienced; and occasionally severe vomiting and purging occur and save the patient. The remedies are emetics, if the physician is called in time, accompanied with the free use of warm drinks, and followed by cathartics. After the evacuation of the alimentary canal, demulcent and nutritive beverages should be given, and the strength of the patient sustained by mild tonics or stimulants. Ether is particularly recommended. (*Merat and De Lens.*)

Some of the poisonous species have been used as medicines; but in this country they are never employed; and too little seems to be precisely known of their modes of action, and their qualities, even in the same species, vary too much, according to the circumstances of their growth and situation, to justify their introduction into the *materia medica*, without further investigation.

MUSK, ARTIFICIAL. *Moschus Factitius.* This is prepared by adding, drop by drop, three parts of fuming nitric acid to one of *unrectified* oil of amber. The acid is decomposed, and the oil converted into an acid resin, which must be kneaded under pure water, until all excess of acid is removed. The substance which remains is the artificial musk, and is of a yellowish-brown colour, viscid, and of an odour which recalls that of musk. It reddens litmus, dissolves sparingly in water, and more freely in alcohol. According to Setterberg, it contains three resins, two of which are soluble in boiling oil of turpentine; the third, insoluble. One of the soluble resins is obtained upon the cooling of the oil, when it separates; the other by evaporating the cold oil from which the first has precipitated. (*Berzelius Traité de Chim.* vi. 714.)

Dr. S. W. Williams, in a paper contained in the Boston Medical and Surgical Journal, gives the following formula for the preparation of artificial musk. Add gradually, drop by drop, *three drachms and a half* of concentrated nitric acid to a *drachm* of rectified oil of amber, contained in a glass tumbler, or very large wineglass. The mixture grows hot, and emits offensive fumes which the operator must avoid. When the ordinary nitric acid is employed, which is not of full strength, the reaction must be assisted by heat; in which case Dr. Williams recommends that the vessel containing the mixed ingredients be placed in a plate before the fire, they being, meanwhile, continually stirred with a glass rod. The reaction is sometimes so violent as to eject part of the contents from the glass. After the mixture has remained at rest for twenty-four hours, it acquires a resinous appearance, and divides into two portions, an acid liquid below, and a yellow resin above, resembling musk in smell. This being thoroughly washed, first with cold and then with hot water, until all traces of acid are removed, is the artificial musk. (*Amer. Journ. of Pharm.* viii. 14.)

Artificial musk is an antispasmodic and nervine, and possesses the general therapeutic properties of the natural substance, though in a weaker degree. It is praised by Dr. Williams, from his personal experience, in the treatment of whooping-cough, typhoid states of fever, and nervous diseases generally. When combined with water of ammonia, compound spirit of lavender, or laudanum, he has found no remedy so efficient in the sinking faintness occurring in the last stage of pulmonary consumption. The average dose for an adult is ten grains; for a child of two years old from half a grain to a grain, repeated, in each case, every two or three hours. It may be prepared as the musk mixture, or with almonds in the form of emulsion. According to Berzelius the tincture is formed by dissolving a *drachm* of artificial musk in an *ounce* of alcohol, equivalent to *ten fluidrachms* of the sp. gr. 0.835. Of this the dose for an adult is a teaspoonful. The tincture recommended in the American Journal of Pharmacy (a *drachm* of the musk to four ounces of alcohol) is altogether too spirituous. Though artificial musk is not equal in power to the natural substance when genuine, yet it is in all probability superior to the adulterated article, so frequently sold under the name of musk. On this account, as well as in view of its comparative cheapness, it forms a useful substitute for musk, applicable to several forms of disease.

MYROBALANS. *Myrobalani.* These are the fruits of various East India trees, particularly of different species of *Terminalia*. They are noticed here partly on account of their ancient reputation, partly because they are still occasionally to be found in the shops, though seldom, if ever, used in medicine. Five varieties are distinguished by authors. 1. *Myrobalani belliricæ*. These are obtained from the *Terminalia Bellirica*. They are roundish or ovate, from the size of a hazelnut to that of a walnut, of a grayish-brown colour, smooth, marked with five longitudinal ribs, and sometimes furnished with a short thick footstalk. They consist of an exterior, thin, firm, resinous, brown, fleshy portion, and an interior kernel, which is light brown, inodorous, and of a bitterish very astringent taste. 2. *Myrobalani chebulæ*. This variety is produced by the *Terminalia Chebula*. The fruit is oblong, pointed at each extremity, from fifteen to eighteen lines in length, of a dark-brown colour, smooth and shining, with five longitudinal wrinkles, but without footstalks. In their internal arrangement and their taste, they resemble the preceding. 3. *Myrobalani citrinæ, vel flavæ*. These are from a variety of the same tree which affords the last mentioned myrobalans, from which they differ only in being somewhat smaller, of a light brown or yellowish colour, and of a taste rather more bitter. They have been sometimes sold in the shops in Philadelphia under the name of *white galls*, to which, however, they bear no other resemblance than in taste. 4. *Myrobalani Indicæ, vel nigræ*. These are thought to be the unripe fruit of the *Terminalia Chebula*, or *T. Bellirica*. They are ovate oblong, from four to eight lines long, and from two to three lines thick, of a blackish colour, wrinkled longitudinally, and presenting, when broken, a thick, brown mass, without kernel, but with a small cavity in the centre. They are sourish and very astringent. 5. *Myrobalani emblicæ*. This variety is wholly different from the preceding, and derived from a plant having no affinity to the *Terminaliæ*—namely, the *Phyllanthus Emblica* of Linnæus. It is often in segments, as kept in the shops. When the fruit is entire, it is blackish, spherical, depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, with a strongly astringent and acedulous taste.

These fruits were in high repute with the Arabians, and were long employed by European practitioners as primarily laxative, and secondarily astringent, in various complaints, particularly diarrhœa and dysentery. Their dose was from two drachms to an ounce. They are not now employed as medicines. We have been told that

they have sometimes been used as a substitute for galls in the preparation of ink-powder.

NAPLES YELLOW. A yellow pigment prepared by calcining a mixture of lead, common sulphuret of antimony, dried alum, and muriate of ammonia, or a mixture of carbonate of lead, diaphoretic antimony, dried alum, and muriate of ammonia. (*Gray.*)

NARCISSUS PSEUDO-NARCISSUS. *Daffodil.* This well known bulbous plant is a native of Europe, but is very common in the gardens of this country, where it attracts attention by the early appearance of its conspicuous yellow flowers. Both the bulb and flowers have been used in medicine. The latter have a feeble peculiar odour, and both have a bitter mucilaginous taste. They are emetic, though uncertain in their operation. It is probable that the flowers of the wild plant are more powerful than those of the cultivated. They may be given dried and powdered, or in the form of extract. The dose of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from a scruple to two drachms; while the extract is said to vomit in the dose of two or three grains. It is conjectured that the emetic property is developed by the agency of water. The bulb is most powerful in the recent state, and, within our own knowledge, is occasionally used as an emetic in domestic practice in this country. When dried and powdered, it has been given in the dose of thirty-six grains without vomiting. The flowers are said also to possess antispasmodic powers, and have been used in France, with supposed advantage, in whooping-cough, epilepsy, and other convulsive affections. It is probable, however, that they operated in these cases by their nauseating or emetic property. They have, moreover, been advantageously employed in diarrhœa, dysentery, and intermittent fever. Other species of *Narcissus* are said to possess the same properties, though they have not been so much used.

NARD. *Spikenard.* Several aromatic roots were known to the ancients under the name of *nardus*, distinguished, according to their origin or place of growth, by the names of *nardus Indica*, *nardus Celtica*, *nardus montana*, &c. They are supposed to have been derived from different species of *Valeriana*. Thus the *nardus Indica* is referred to the *V. Jatamensi* of Bengal, the *nardus Celtica* to the *V. Celtica*, inhabiting the Alps, Apennines, &c., and the *nardus montana* to the *V. tuberosa*, which grows in the mountains of the South of Europe. The Indian nard, or spikenard, sometimes also called Syrian nard, is still occasionally to be found in the shops. It is a small, delicate root, from one to three inches long, beset with a tuft of soft, light brown, slender fibres, of an agreeable odour, and a bitter, aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of the official valerian.

NASTURTIIUM OFFICINALE. *R. Brown.* *Sisymbrium Nasturtium*, Linn. *Water-cress.* A small, perennial, herbaceous, succulent plant, growing in springs, rivulets, and ponds, in North America, Europe, and some parts of Asia. The fresh herb has a quick penetrating odour, especially when rubbed, and a bitterish, pungent taste, but loses both when dried. In sensible and medical properties it bears some resemblance to scurvy-grass, though milder, and on this account is preferred for the table. It is thought to be useful in scorbutic affections, and visceral obstructions. The expressed juice is sometimes given in the dose of one or two ounces; but the herb is more frequently used in the form of a salad. Other species of *Nasturtium*, as the *N. palustre* or *marsh water-cress*, and the *N. amphibium* or *water-radish*, grow in similar situations with the *N. officinale*, and possess similar virtues.

NIGELLA SATIVA. *Nutmeg flower.* *Small fennel-flower.* A small annual plant, growing wild in Syria and the South of Europe, and cultivated in various parts of the world. The seeds, which are sometimes kept in the shops under the name of *semen nigellæ*, are ovate, somewhat compressed, about a line long and half as broad, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odour, like that of nutmegs, and a spicy pungent taste. Their chief constituents are a volatile and fixed oil. They are analogous to the other aromatics in properties, and though not at present used in medicine, have been employed in some countries from the remotest times as a condiment.

NITRATE OF SODA. *Cubic Nitre.* This salt may be formed by treating carbonate of soda with nitric acid. It exists naturally, in inexhaustible quantities, in the desert of Atacama in Peru, where it forms a bed of variable thickness, covered with

clay, of one hundred and fifty miles in extent. Considerable quantities have been extracted for the purposes of commerce. Occasionally a cargo is brought to the United States.

Nitrate of soda, when pure, is a white salt, crystallizing in rhomboidal prisms, and having a sharp, cooling, and bitter taste. It attracts moisture slightly from the air, and dissolves in about twice its weight of water at 60°. It has been praised as a remedy in dysentery by two German physicians, Drs. Velsen and Meyer, given in the quantity of from half an ounce to an ounce in the course of the day, dissolved in gum water, or other mucilaginous liquid. The crude salt, as it comes from Peru, is in dirty-white saline lumps, rather soft and friable, and damp on the surface. It is cheaper than nitre, for which salt it may be substituted in the manufacture of sulphuric acid, and in the preparation of nitric acid, chrome yellow, &c.

As nitrate of soda has been imposed upon our merchants for nitre, it may be useful to mention that the former salt may be distinguished by its giving rise to an orange-yellow flame when thrown on burning coals, and by the rhomboidal shape of its crystals; those of nitre being long six-sided prisms. (See page 569.)

NITROSULPHATE OF AMMONIA. This compound, discovered by Pelouze in 1835, may be formed by passing nitric oxide through a solution of sulphite of ammonia in five or six times its volume of liquid ammonia. A large number of crystals are formed, which must be quickly washed with liquid ammonia previously refrigerated, and dried without heat. Nitrosulphate of ammonia has been used at the Hotel Dieu in Paris, in doses of twelve grains, with apparent advantage, in typhoid fevers. Its composition corresponds with one equiv. of nitric oxide, one of sulphurous acid, and one of ammonia; but as the salt is not precipitated by barytic water, Pelouze conceives that the nitric oxide and sulphurous acid, together, form a peculiar acid which he calls *nitrosulphuric acid*, consisting of one eq. of nitrogen, one of sulphur, and four of oxygen.

NYPHÆA ODORATA. *Sweet-scented Water-lily.* An indigenous herbaceous perennial, growing in most parts of the United States, in fresh-water ponds and the borders of streams, and distinguished by the beauty and delicious odour of its large, white, many petaled flowers. Its root is, when fresh, large and fleshy, but becomes light, spongy, and friable by drying. It is very astringent and bitter; and, according to Dr. Bigelow, contains much tannin and gallic acid. It is sometimes employed, in the form of poultice, as a discutient application. The root of the *Nymphæa alba*, or European *white water-lily*, was esteemed aphrodisiac by the ancients; but has long lost this reputation. Like that of the American plant, it is bitter and styptic, and may have been useful by its astringency in some cases of leucorrhœa, gonorrhœa, dysentery, &c., in which it was formerly employed for its reputed sedative virtues.

OCHRES. These are native mixtures of argillaceous or calcareous earth and oxide of iron, employed in painting. They are prepared for use by agitating them with water, decanting the turbid liquor after the coarser particles have subsided, then allowing it to rest in order that the finer parts may be deposited, and lastly drying the sediment which forms. The colour of the ochres varies with the state of oxidation of the iron, and with the proportion which it bears to the other ingredients, and is sometimes artificially modified by the agency of heat. Several varieties are kept in our shops, under different names, according to their colour, or place of origin. Such are the *brown ochre*, the *yellow ochre*, the *red ochre*, the *Roman ochre* of a brownish-yellow changing by heat to a purple red, the *Oxford ochre* of a brownish-yellow colour less deep than the Roman, and the *French ochre* which is yellow. The *Indian red* from the Persian Gulf, and *Spanish brown*, may also be ranked in this class of pigments. Sometimes ochres come in a powdery state, and sometimes in hard masses; in the latter state they are called *stone ochres*.

OCIMUM BASILICUM. *Basil.* An annual plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. The whole plant has a strong, peculiar, agreeable, aromatic odour, which is improved by drying. The taste is aromatic, and somewhat cooling and saline. Basil has the ordinary properties of the aromatic plants, and is in some places considerably used as a condiment. The seeds are said by Ainslie to be used in India, in the form of infusion, as a remedy in gonorrhœa and nephritic affections.

ŒNANTHE CROCATA. *Hemlock Water-dropwort.* A perennial, umbelliferous, aquatic, European plant, exceedingly poisonous both to men and inferior animals. The root, which has a sweetish not unpleasant taste, is sometimes eaten by mistake for other roots, with the most dangerous effects; and numerous instances of fatal results are on record. The symptoms produced are such as attend irritation or inflam-

ination of the stomach, united with great cerebral disturbance. Externally applied the root produces redness and irritation of the skin, with an eruptive affection. It is said to be sometimes used empirically as a local remedy in piles; and a case is recorded in which an obstinate leprosy was cured by the continued use of the juice of the plant. Other species of *Enanthe* are poisonous, and the whole genus should be regarded among the suspected plants. We have two or three indigenous species. The proper remedies, in cases of poisoning from these plants, are emetics, followed, after the stomach has been thoroughly evacuated, by mucilaginous and other demulcent drinks.

GENOTHERA BIENNIS. *Tree Primrose.* A biennial indigenous plant, growing in fields and along fences, from Canada to Carolina. It is from two to five feet high, with a rough stem, alternate, ovate-lanceolate leaves, and fine yellow flowers, which make their appearance in July and August. Schoepf states that it is esteemed useful as a vulnerary. Dr. R. E. Griffith, late of the University of Virginia, has found a strong decoction of the small branches, with the leaves and cortical part of the stem and larger branches, very beneficial in eruptive complaints, especially tetter. He applies the decoction several times a day to the affected part. He thinks the virtues of the plant reside in the cortical part, which has a mucilaginous taste, and leaves a slight sensation of acrimony in the fauces. (*Journ. of the Phil. Col. of Pharm.* iv. 292.)

OIL OF EUPHORBIA. A fixed oil, obtained from the seeds of the *Euphorbia Lathyris*, a biennial plant growing wild in this country, though believed to have been introduced from Europe, where it is indigenous. It is often found near gardens and in cultivated fields, and is generally called *mole-plant*, under the impression that moles avoid the grounds where it grows. (*Pursh.*) It is the *Caper plant* of England. (*Loudon's Encyc. of Plants.*) Like the other species of *Euphorbia*, it contains a milky juice, which is extremely acrid; and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in regular practice. This may be extracted by expression, or by the agency of alcohol or of ether. In the first case, the bruised seeds are pressed in a canvass or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposits upon standing, and by subsequent filtration. By the latter process, the bruised seeds are digested in alcohol or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeiran, however, the oil obtained by these different processes is by no means identical. That procured by expression is probably the purest.

Oil of euphorbia is colourless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acrimony. Soubeiran has ascertained that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (*Journ. de Pharm.* xxi. 259.) From 40 to 44 parts are obtained by expression from 100 of the seed.

This oil is a powerful purge, operating with much activity in a dose varying from five to ten drops. It has within a few years been much used by some Italian and French physicians, who have not found it to produce inconvenient irritation of the stomach and bowels. Its want of taste, and the smallness of the dose, recommend it especially in the cases of infants. It is said to be less acrid and irritating than the croton oil, over which it also has the advantage of greater cheapness. Some trials which have been made with it on this side of the Atlantic have not tended to confirm these favourable reports. It was found uncertain in its cathartic effect, and very liable to vomit. (Scattergood, *Journ. of the Phil. Col. of Pharm.* iv. 124.) It may be given in pill with the crumb of bread, or in emulsion.

OIL OF JASMINE. This oil is obtained from the flowers of the *Jasminum officinale*, or common *white jasmine*, and from those also of the *J. Sambac* and *J. grandiflorum*. Alternate layers of the fresh flowers, and of cotton saturated with the oil of ben (expressed oil of *Hyperanthera Moringa*), or perhaps other fixed oil, are exposed in a covered vessel to the warmth of the sun, the flowers being occasionally renewed, till the oil becomes impregnated with their odour, when it is separated from the cotton by pressure. This method is necessary, as the flowers do not yield their aroma by distillation. The oil of jasmine is used only as a perfume.

ORANGE RED. *Orange Mineral. Sandix.* Red oxide of lead, prepared by calcining carbonate of lead. It is of a brighter colour than *minium*, and is used as a pigment.

OROBANCHE VIRGINIANA. *Epifagus Americanus*, Nuttall. *Beech-drops. Cancer-root.* A parasitic, fleshy plant, with a tuberous, scaly root, and a smooth stem,

branched from the base, from twelve to eighteen inches high, furnished with small ovate scales, of a yellowish or purplish colour, and wholly destitute of verdure. It is found in all parts of North America, growing upon the roots of the beech tree, from which it obtained its popular name. It is in some places very abundant. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful in obstinate ulcers of a cancerous character, to which it is directly applied in the state of powder. The late Professor Barton conjectured that it was an ingredient of a secret remedy, at one time famous as *Martin's cancer powder*, of which, however, the most active constituent was arsenious acid.

Other species of *Orobanche*, growing in America and Europe, have been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter nauseous taste. In Europe they are called *broom-rape*. The *O. Americana* and *O. uniflora*, of this country, are said to be used for the same purposes as the species above noticed, and like it are called *cancer-root*.

ORPIMENT. *King's Yellow.* A native sulphuret of arsenic, consisting of two equiv. of metal 75·4, and three equiv. of sulphur 48·3 = 123·7. It is in masses of a brilliant lemon-yellow colour, composed of flexible laminæ, and slightly translucent. It exists in various parts of the world, but is obtained for use from Persia and China. (*Guibourt.*) It is sometimes mixed with realgar, which gives it a reddish or orange hue. A similar sulphuret may be made artificially by passing sulphuretted hydrogen through a solution of arsenious acid in muriatic acid. There is reason to believe that neither the native sulphuret, nor the artificial, when prepared in the manner just mentioned and well washed, is poisonous, at least in a degree at all comparable to other arsenical compounds.

Artificial orpiment is prepared for use by fusing together equal parts of arsenious acid and sulphur. (*Turner.*) In Germany, according to Guibourt, it is prepared by subliming a mixture of these two substances. In this case, however, it retains a large portion of the acid undecomposed, and is therefore highly poisonous. Guibourt found a specimen which he examined to contain 96 per cent. of arsenious acid, and only 6 per cent. of the sulphuret of arsenic.

Orpiment is an ingredient of certain depilatories. Atkinson's depilatory is said to consist of one part of orpiment and six parts of quicklime, with some flour and a yellow colouring matter. (*Ann. der Pharm.* xxxiii. 348.) But this arsenical sulphuret is chiefly used in fireworks, and as a pigment.

ORYZA SATIVA. *Rice.* This is an annual plant, originally, perhaps, derived from the East Indies, but now cultivated in all parts of the globe where the climate and soil are adapted to its growth. The rice of commerce consists of the seeds of the plant deprived of their husk. Carolina rice was found by Braconnot to contain 85·07 per cent. of starch, 3·60 of gluten, 0·71 of gum, 0·29 of uncrystallizable sugar, 0·13 of fixed oil, 4·80 of vegetable fibre, 5·00 of water, and 0·40 of saline substances. This grain is highly nutritious, and of easy digestion, and constitutes the almost exclusive diet of whole nations. Being wholly free from laxative properties, it is admirably adapted to cases of weak bowels, in which there is a strong tendency to diarrhœa. Care, however, should be taken that it be boiled till it becomes soft. A decoction of rice, usually called *rice-water*, is a good nutritive drink in fevers and inflammatory affections of the bowels, lungs, and kidneys. There appears to be no ground for the opinion, which has been entertained by some, that a diet of rice is injurious to the eyes.

OXALIC ACID. *Acidum Oxalicum.* This acid is found both in animals and vegetables. It is generated occasionally in consequence of a diseased action in the kidneys, and deposited in the bladder as oxalate of lime, forming a peculiar concretion, called from its appearance the mulberry calculus. In vegetables, it occurs in a free state in the bristles of the chick-pea (*Cicer arietinum*), combined with potassa as a supersalt in the *Rumex acetosa* or common sorrel, and the *Oxalis Acetosella* or wood sorrel, and united with lime in several species of lichen, and in the roots of rhubarb, valerian, and several other plants. It is from the generic appellation *Oxalis*, that it takes its name.

Preparation. This acid may be prepared, by proper management, from the juice of the wood sorrel. The first step is to obtain the binoxalate of potassa in crystals, by a careful evaporation of the juice of the plant. The excess of acid is then neutralized with carbonate of potassa, and the neutral oxalate is decomposed by acetate of lead. In consequence of a double decomposition, a precipitate of oxalate of lead is obtained. This is to be well washed and dried, and decomposed by means of one-

third of its weight of strong sulphuric acid, previously diluted with ten times its weight of water. An insoluble sulphate of lead is formed, and the oxalic acid, being liberated, may be made to crystallize by evaporation. The mother waters, by further evaporation, furnish fresh portions of crystals, until quite exhausted. By this process a very pure acid may be obtained.

The usual process for obtaining oxalic acid consists in decomposing sugar by nitric acid. Four parts of sugar are acted upon by twenty-four parts of nitric acid of the sp. gr. 1.22, and the mixture heated so long as any nitric oxide is disengaged. A part of the carbon of the sugar is converted into carbonic acid, by oxygen derived from the nitric acid, which is thereby partially converted into nitric oxide. The undecomposed nitric acid, reacting on the remaining elements of the sugar, generates oxalic and saccharic (oxalhydic) acids, the former of which crystallizes as the materials cool, while the latter remains in solution. The crystals being removed, a fresh crop may be obtained by further evaporation. The thick mother water which now remains is a mixture of saccharic, nitric, and oxalic acids; and by treatment with six times its weight of nitric acid, the greater part of the saccharic acid will be converted into oxalic acid. The new crop of crystals, however, will have a yellow colour, and contain a portion of nitric acid, the greater part of which may be got rid of by allowing them to effloresce in a warm place.

Many substances besides sugar yield oxalic acid, by the action of nitric acid; as for example molasses, potato starch, gum, wool, hair, silk, and many vegetable acids. In every case in which it is thus generated, the proportional excess of oxygen which it contains, compared with every other organic compound, is furnished by the nitric acid. Organic substances yield oxalic acid also, when heated with potassa. Thus shavings of wood, if mixed with a solution of caustic potassa, and exposed to a heat considerably higher than 212° , will be partially decomposed and converted into oxalic acid, which then combines with the alkali. This process constitutes, perhaps, the cheapest method of obtaining oxalic acid.

Properties. Oxalic acid is a colourless crystallized solid, possessing considerable volatility, and a strong, sour taste. Its crystals have the shape of slender, flattened, four or six-sided prisms, with two-sided summits; and, when exposed to a very dry atmosphere, undergo a slight efflorescence. It dissolves in about nine times its weight of cold, and in its own weight of boiling water. The solution of the crystals takes place with slight crepitation. It dissolves also, but not to the same extent, in alcohol. The presence of nitric acid renders it more soluble in water. It combines with salifiable bases, and forms salts called oxalates. The most interesting of these are the three oxalates of potassa, severally called oxalate, binoxalate, and quadroxalate, and the oxalate of lime. The quadroxalate, sold under the name of binoxalate of potassa or *salt of sorrel*, sometimes absurdly called the *essential salt of lemons*, is employed for removing iron moulds from linen, and acts by its excess of acid, which forms a soluble salt with the sesquioxide of iron constituting the stain. Oxalic acid is used for removing ink stains and iron moulds, for cleaning the leather of boot-tops, and for discharging colours in calico-printing.

This acid has a very strong affinity for lime, and forms with it an insoluble precipitate consisting of oxalate of lime, whenever the acid and earth are brought into contact. Hence, oxalic acid and its soluble combinations are the best tests we possess for lime; and conversely, a soluble salt of lime for oxalic acid. When lime is searched for, the oxalate usually employed is the oxalate of ammonia, as being the most convenient. So strong is the mutual attraction between this acid and lime, that the former takes the latter, even from sulphuric acid. Hence, the addition of a soluble oxalate disturbs the transparency of a solution of sulphate of lime.

Oxalic acid is distinguished from all other acids, by the form of its crystals, and by its solution yielding a precipitate with lime-water, insoluble in an excess of the acid.

Composition. Oxalic acid consists of two eqs. of carbon 12.24, and three of oxygen 24=36.24. When crystallized, three eqs. of water 27 must be added, making the eq. of the crystals 63.24. Two eqs. of this water may be driven off by a regulated heat, by which the acid is made to effloresce, but the third cannot be expelled without destroying the acid itself. Accordingly, as in the case of nitric acid, we have no knowledge of anhydrous oxalic acid in an uncombined state.

From the constitution of oxalic acid, as above given, it is plain that this acid corresponds in composition to carbonic acid and oxide taken together, and is, therefore, intermediate, in the quantity of oxygen which it contains, between this acid and oxide. Notwithstanding it contains less oxygen than carbonic acid, it is incomparably stronger as an acid, which circumstance may be accounted for by supposing some

peculiarity in the mode in which its constituents are combined. The composition of the acid not only corresponds with the united constituents of carbonic acid and oxide, but there is reason to believe that these two compounds are actually its proximate constituents; for if treated with strong sulphuric acid, the whole of the water will be abstracted, and the elements of the dry oxalic acid will be instantly resolved into equal volumes of carbonic acid and carbonic oxide.

Oxalic acid combines with salifiable bases in two principal ways. Sometimes it drops its essential equivalent of water, which at other times it retains. Thus the oxalate of lead is a compound of the dry acid and the protoxide of lead; while the oxalate of lime retains the one equivalent of water.

Medical and Toxicological Properties. According to Dr. A. T. Thomson, oxalic acid in small doses, largely diluted with water and sweetened to the taste, forms an agreeable, cooling beverage, which may be used in febrile diseases as a substitute for lemonade. M. Nardo recommends it as an antiphlogistic and anodyne in inflammation of the mucous membranes, given in the dose of a grain and a half dissolved in eight fluidounces of liquid. Notwithstanding the safety of its employment in medicinal doses, it is a virulent poison, producing death with great rapidity and certainty. Instances are on record of its proving fatal in ten minutes, and few survive the effects of a poisonous dose beyond an hour. As this acid is generally kept in the shops, and not a few instances are on record of its fatal effects, when taken by design, or by mistake for Epsom salt, we shall feel ourselves justifiable in being somewhat full on its toxicological relations.

Oxalic acid was first noticed as a poison by Mr. Royston in 1814; since which time it has been principally investigated in this relation by Dr. A. T. Thomson of London, Dr. Percy of Lausanne, Dr. Coindet of Geneva, and Dr. Christison of Edinburgh. Since its properties of certainty and rapidity as a poison have been more generally known, its employment for committing suicide has become more frequent.

From the general resemblance which the crystallized oxalic acid bears to Epsom salt, many fatal mistakes have occurred, since the acid has become so extensively an article of commerce, in consequence of its being sold for that saline purgative. Nothing, however, can be easier than to distinguish them; for upon tasting a minute portion of the acid, which may be done with perfect safety, it will be found strongly sour, whereas the salt in question is bitter. Unfortunately, however, in the instances of these fatal mistakes, no suspicions being awakened, the solution is swallowed with the greatest rapidity, and the mischief is done before the victim is aware of his danger.

Oxalic acid acts on the economy in two principal ways, according as its solution is concentrated or dilute. When concentrated, it causes exquisite pain, followed by violent efforts to vomit; then sudden dulness, languor, and great debility, and finally death without a struggle. When dilute, it acts in a totally different manner. Dissolved in twenty times its weight of water, it possesses no corrosive, and hardly any irritating power, and yet it operates as a deadly poison, causing death by acting on the brain, spinal marrow, and heart.

The morbid appearances caused by oxalic acid are various. In a dissection reported by Dr. Christison, the mucous coat of the throat and gullet had an appearance as if scalded, and that of the gullet could be easily scraped off. The inner part of the stomach was pultaceous, in many points black, in others red, and that of the intestines, similarly but less violently affected. In another case recorded by the same author, the whole villous coat of the stomach was either softened or removed, as well as the inner membrane of the œsophagus; so that the muscular coat was exposed, and this coat exhibited a dark gangrenous appearance, being much thickened, and highly injected. The stomach usually contains a dark fluid, resembling coffee-grounds, consisting chiefly of altered blood. In a few cases after death by this acid, no morbid appearances have been discovered.

In the treatment of poisoning by oxalic acid, the remedial measures must be employed with great promptitude. If the antidotes are not at hand and vomiting is not free, emetics will be proper. The stomach pump would be useful, but no delay in the application of other remedies is admissible, in the expectation of its use. Dr. Christison objects to the use of warm water to promote vomiting, from a fear that it would increase the danger by promoting the absorption of the poison; but it may be a question whether this evil, considering the incidental benefit of the water in promoting vomiting, is not less than that of the corrosion of the stomach, which copious dilution has a tendency to prevent. The proper antidote is chalk or magnesia, mixed with water; and as soon as either can be procured, it must be administered in large and frequently repeated doses. Chalk was first proposed for this purpose by Dr. A.

T. Thomson, of London. These substances act by neutralizing the poison, forming with it an insoluble oxalate either of lime or of magnesia, both of which are inert. The soluble salts of oxalic acid, as the oxalate of ammonia, and the oxalates of potassa, are likewise poisonous, and the antidotes for them are the same as for the acid.

The best tests for the detection of oxalic acid in the contents of the stomach or in the vomited matter, in cases of suspected poisoning by this acid, are chloride of calcium, sulphate of copper, and nitrate of silver. The first causes a white precipitate of oxalate of lime, known by its being soluble in nitric acid; the second, a bluish-white precipitate of oxalate of copper; and the third, a dense white precipitate of oxalate of silver, which, when dried and heated, becomes brown and detonates faintly. When the antidotes have been freely used during life, the poison will be in the state of oxalate either of lime or magnesia. Here the oxalate found is to be boiled with a solution of carbonate of potassa, whereby an oxalate of potassa will be generated; and this must then be examined by the re-agents above indicated.

OX-GALL. *Fel Bovinum.* The bile of the ox is a viscid fluid, of a green or greenish-yellow colour, a peculiar nauseous odour, and a bitter taste. According to Gmelin, it contains, besides water, 1. a volatile principle, having the odour of musk; 2. a peculiar fatty matter, originally found in biliary calculi, called *cholesterin*; 3. oleic acid; 4. margaric acid; 5. a new acid, called *cholic acid*; 6. a bitter resinous substance, called *biliary resin*; 7. a crystalline principle, called *taurin*; 8. *biliary sugar*; 9. a *colouring substance* upon which the characteristic colour of the bile depends; 10. a kind of extractive matter; 11. a substance analogous to vegetable gluten; 12. caseous matter; 13. salivary matter; 14. albumen; 15. mucus; 16. various saline substances. The resin and sugar, with the colouring matter, appear to be the characteristic constituents. Gmelin considers the *piromel* of Thenard as a mixture of the sugar of the bile with a portion of the resin which it renders soluble in water.

Bile was formerly highly valued as a remedy in numerous complaints, and was considered peculiarly applicable to cases attended with deficient biliary secretion. It is supposed to be tonic and laxative. It is prepared for use by evaporating it to the consistence of an extract. The dose is from five to ten grains. *Refined ox-gall*, much used by limners and painters, is prepared, according to Gray, in the following manner. Take of "fresh ox-gall one pint; boil, skim, add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months, then decant off the clear; mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colourless."

OXIDE OF SILVER. *Argenti Oxidum.* This oxide has been proposed as a substitute for nitrate of silver, as having the therapeutic action of the latter, without its escharotic effect, and its objectionable power of discolouring the skin. It is most conveniently prepared by adding a solution of caustic potassa in excess to one of nitrate of silver. The precipitate thrown down is to be carefully washed and dried, and kept from the air and light. It is an olive-brown powder. When approaching to black it is of bad quality, and is irritant and even caustic. It consists of one eq. of silver and one of oxygen.

Medical Properties. Oxide of silver was first employed in medicine by Van Mons and Sementini. More recently it has been recommended by Mr. C. H. B. Lane, who considers it to act as a sedative. Mr. Lane has used it with more or less success in nausea, cardialgia, pyrosis, various painful affections of the stomach independent of organic lesion, dysentery, diarrhœa, night sweats without other obvious affection, dysmenorrhœa, menorrhagia, leucorrhœa, chronic enlargement of the uterus, attended with flooding, &c. It appeared that the oxide exerted a peculiar control over uterine fluxes. Some of the cases treated required the use of tonics after the salutary influence of the oxide had been exerted. Dr. Golding Bird has also obtained favourable effects from the use of the oxide of silver, and confirms to a certain extent the results of Mr. Lane, especially as to its valuable powers in menorrhagia. Thus far no case of cutaneous discoloration has occurred, though Mr. Lane has given the oxide repeatedly for two months, and Dr. Bird in more than a hundred cases, in one for four months. Mr. Lane has observed one case in which repeated salivation occurred, and Dr. Bird, several in which the gums were affected. In stomach disease, characterized by a glairy discharge, instead of a watery one, this physician derived not the slightest benefit from the oxide, though he used it in thirty cases. In epilepsy it is supposed that the oxide will accomplish all that can be expected from the nitrate, with less risk to the stomach, and without incurring the danger of blackening the skin. The dose of oxide of silver is half a grain, twice or thrice a day, given in pill.

In no case did Mr. Lane carry the dose beyond six grains in the twenty-four hours. It has been used in the form of ointment, composed of from five to ten grains to the drachm of lard, as an application to venereal sores, and to the urethral membrane in gonorrhœa, smeared on a bougie.

PÆONIA OFFICINALIS. *Peony.* This well known plant is a native of Southern Europe, but is everywhere cultivated in gardens for the beauty of its flowers. The root, flowers, and seeds were formerly official. The root consists of a caudex about as thick as the thumb, which descends several inches into the ground, and sends off in all directions, spindleshaped tubers that gradually taper into thread-like fibres, by which they hang together. It has a strong, peculiar, disagreeable odour, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acrid. The odour disappears or is much diminished by drying. Peony-root was in very great repute among the ancients, who used it both as a charm and as a medicine in numerous complaints, particularly epilepsy. In modern times it has also been given in epilepsy and various nervous affections, but is at present seldom used. The dose of the fresh root is from two drachms to an ounce, boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried. The expressed juice of the recent root is recommended in the dose of an ounce. It is milky, of a strong odour, and very disagreeable taste. The flowers are usually of a deep-red colour, though in some varieties of a light-red, and even whitish. They have, when fresh, an odour similar to that of the root, but feebler, and an astringent, sweetish, herbaceous taste. When dry, they are inodorous. As a medicine they have little power, and are scarcely used. The seeds are roundish oval, about as large as a pea, externally smooth, shining, and nearly black, internally whitish, inodorous when dry, and of a mild, oleaginous taste. By some authors they are said to be emetic and purgative, and by others are considered antispasmodic. They may be given in the same dose with the root, but are not used in regular practice.

PALM OIL. This highly valuable fixed oil is the product of the *Elais Guiniensis*, a palm growing on the Western coast of Africa, and cultivated in the West Indies and South America. It is among the handsomest trees of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia, and other places on the African coast, though prepared also in the West Indies, Cayenne, and Brazil. It is not improbable that various species of palms contribute to the supply of this article of commerce.

Palm oil has the consistence of butter, a rich orange-yellow colour, a sweetish taste, and an agreeable odour, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid and of a whitish colour. It melts with the heat of the hand, and when perfectly fluid passes readily through blotting paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. According to M. Henry, it consists of 31 parts of stearin and 69 of olein. But from the experiments of Frémy and Stenhouse, it appears that the stearin has peculiar properties entitling it to be considered as a distinct principle, and has accordingly received the name of *palmitin*. This is converted into *palmitic acid* by saponification. (*Kane's Chem.*) It appears also that a considerable proportion of this acid, together with some glycerin, exists uncombined in the oil, as ascertained by MM. Pelouze and Boudet; so that the changes which are effected in oils, through the agency of alkalies, in the process of saponification, takes place, to a certain extent, spontaneously in palm oil. (*Journ. de Pharm.* xxiv. 389.) Hence it is more easily saponified than any other fixed oil. It is said to be frequently imitated by a mixture of lard and suet, coloured with turmeric, and scented with Florentine orris. It is much employed in the manufacture of a toilet soap, which retains its pleasant odour. Palm oil is emollient, and has sometimes been employed in friction or embrocation, though not superior for this purpose to many other oleaginous substances.

PARIETARIA OFFICINALIS. *Wall Pellitory.* A perennial European herb, growing on old walls and heaps of rubbish. It is inodorous, has an herbaceous, somewhat rough and saline taste, and contains nitre derived from the walls where it flourishes. It is diuretic and refrigerant, and is said also, but without good reason, to be demulcent and emollient. The ancients employed it in various complaints, and it is still considerably used on the continent of Europe, especially in domestic practice. It is given in complaints of the urinary passages, dropsy, and febrile affections, usually in the form of decoction. The expressed juice is also used, and the fresh plant is applied in the shape of a cataplasm to painful tumours.

PATENT YELLOW. *Mineral Yellow.* A pigment, consisting of chloride combined with protoxide of lead. It is prepared by mixing common salt and litharge with a sufficient quantity of water, allowing the mixture to stand for some time, then washing out the liberated soda, and exposing the white residue to heat.

PAULLINIA. *Guarana.* This is a new medicine introduced into Europe from Brazil, which has attracted some attention from the asserted fact, that it contains a principle identical with caffeine. The name of *paullinia* has been bestowed upon it from the generic title of the plant from which it is obtained. That of *guarana*, by which it was previously known, was derived from a tribe of aborigines, called Guaranis, who are said to use it extensively as a corrigent of their vegetable diet. It is prepared from the seeds of the *Paullinia sorbilis* of Martius, a climbing shrub, belonging to the class and order Octandria Trigynia of the Linnæan system, and the natural family of the Sapindaceæ. The seeds, which are contained in a three-celled, three-valved, coriaceous capsule, are lenticular and almost horny, and invested with a flesh-coloured arillus which is easily separable when dry. They are prepared by powdering them in a mortar or upon a chocolate stone previously heated, mixing the powder with a little water, exposing it for some time to the dew, then kneading it into a paste, mixing with this some of the seeds either whole or merely bruised, and finally forming the mixture into cylindrical or globular masses, which are dried and hardened in the sun or by the smoke of a fire. These masses are of a reddish-brown colour, rugose on the surface, very hard, and of a marbled appearance when broken. Paullinia is of a somewhat astringent and bitterish taste, and in this as well as in its odour, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. Martius found in it a crystallizable principle which he named *guaranin*, and which seems to have been proved by the researches of MM. Berthemot and Dechastelus to be identical with *caffeïn*. The discovery of *caffeïn* in three plants belonging to distinct natural families, namely, the coffee and tea plants, and the Paullinia, is a highly interesting result of recent chemical investigations. It is said to be more abundant in the paullinia than in either of the other vegetables. According to Berthemot and Dechastelus, it exists in the seeds, united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble. Besides these ingredients, the seeds contain also free tannic acid, gum, albumen, starch, and a greenish fixed oil. (*Journ. de Pharm.* xxvi. 514 and 518.)

The effects of paullinia upon the system are said to be those of a tonic; but they do not appear to have been very accurately investigated. It is highly probable, both from its composition and the use made of it by the natives of Brazil, that it has an influence over the nervous system similar to that of tea and coffee. It is habitually employed by the Indians, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink prepared by scraping it and suspending the powder in sweetened water. It is considered by them useful in the prevention and cure of bowel complaints. Dr. Gavrelle, who was formerly physician to Don Pedro, in Brazil, and there became acquainted with the virtues of this medicine, called the attention of the profession to it a few years since in France. He had found it advantageous in the diarrhœa of phthisis, sick-headache, paralysis, tedious convalescence, and generally as a tonic. It may be given in substance, in the quantity of one or two drachms, scraped into powder and mixed with sweetened water; but the most convenient form of administration is that of spirituous extract. According to M. Dechastelus, alcohol is the only agent which completely extracts its virtues; ether and water effecting this object but partially. Of the extract eight or ten grains may be given during the day in the form of pills. Paullinia may also be taken along with chocolate as a drink.

PHELLANDRIUM AQUATICUM, Linn. *Cenanthe Phellandrium*, Lamarck. *Fine-leaved Water-hemlock.* A biennial or perennial, umbelliferous, European water-plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The seeds have been used in Europe to a considerable extent, in the treatment of disease. They are from a line to a line and a half in length, ovate-oblong, narrow above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx and with the erect or reverted styles. Their colour is yellowish-brown, their odour peculiar, strong, and disagreeable; their taste acrid and aromatic. Among their constituents is a volatile oil, upon which their aromatic flavour depends. By different writers they are described as aperient, diuretic, emmenagogue, expectorant,

and sedative. They probably unite mild narcotic properties with the stimulant powers which are common to most of the aromatics, and may be directed, according to circumstances, to different secretory organs. In over doses they produce vertigo, intoxication, and other narcotic effects. The complaint in which they appear to have been used most successfully is consumption, probably of the catarrhal character. They have been given also in asthma, dyspepsia, intermittent fever, obstinate ulcers, &c. The dose of the seeds, to commence with, is five or six grains, so repeated as to amount to a drachm in twenty-four hours. They should be given in powder.

PHLORIDZIN. This is a bitter principle, discovered by Dr. Konink, of Germany, in the bark of the apple, pear, cherry, and plum trees. It is most abundant in the bark of the root, and derived its name from this circumstance. (From two Greek words, φλοιος bark, and ρίζα a root.) It is light, white, crystallizable in silky needles, of a bitter taste, soluble in about 1000 parts of cold and in all proportions in boiling water, very soluble in alcohol, scarcely soluble in ether cold or hot, dissolved without change by solutions of the alkalies, especially by ammonia, deprived of its water of crystallization at 212°, and fusible at a somewhat higher temperature. It is without acid or alkaline reaction, and consists of carbon, hydrogen, and oxygen. To obtain it, the fresh bark of the root of the apple tree should be selected, as the dried bark is said to contain it in much smaller proportion. The bark is to be boiled for an hour or two successively in two separate portions of water, each sufficient to cover it, and the decoctions set aside. At the end of thirty hours they will have deposited a considerable quantity of coloured phloridzin, which may be purified by boiling for a few minutes with distilled water and animal charcoal, filtering, repeating this process two or three times, and then allowing the solution to cool slowly. The phloridzin is deposited in the crystalline state. An additional quantity may be obtained by evaporating the decoction to one-fifth of its bulk, allowing it to cool, and purifying the substance deposited in the same manner as before.

Phloridzin is said to possess the anti-intermittent property in a high degree, and to have proved successful where quinia had failed. It was employed by Dr. Konink in the dose of ten or fifteen grains, and in this quantity effected cures in several cases of intermittent fever. (*Journ. de Pharm.* xxii. 78.)

PHYSALIS ALKEKENGI. *Common Winter Cherry.* A perennial herbaceous plant, growing wild in the South of Europe, and cultivated in our gardens. The fruit is a round red berry, about as large as a cherry, enclosed in the calyx, and containing numerous flat kidney-shaped seeds. The berries are very juicy, and have an acidulous, bitterish taste. The calyx is very bitter. By drying they shrink, and become of a brownish-red colour. They are said to be aperient and diuretic, and have been highly recommended in suppression of urine, gravel, and other complaints of the urinary passages. From six to twelve cherries, or an ounce of the expressed juice, may be taken for a dose; and even much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food. The berries of the *Physalis viscosa*, of this country, are said by Clayton to be remarkably diuretic.

PICHURIM BEANS. The seeds of a tree not well known, growing in Brazil, Guiana, Venezuela, and other parts of South America. The tree has been supposed to be the *Ocotea Pichurim* of Kunth (*Laurus Pichurim*, Richard, *Aydendron Laurel*, Nees); but this is positively denied by F. Nees von Esenbeck; and the brother of that botanist refers the seeds to the *Nectandra Puchury*. The beans are the kernels of the fruit separated into halves. They are ovate-oblong or elliptical, flat on one side, convex on the other, of a grayish-brown colour externally, chocolate coloured within, of an aromatic odour between that of nutmegs and sassafras, and of a spicy pungent taste. There are two kinds, one about an inch and a half long by half an inch in breadth, the other little more than half as large, rounder, and of a dark-brown colour. Their virtues depend on a volatile oil. In medical properties they resemble the aromatics in ordinary use, and may be employed for the same purposes. They are very rare in this country.

PIMPINELLA SAXIFRAGA. *Small Burnet Saxifrage.* *Saxifraga.* A perennial umbelliferous European plant, growing on sunny hills, and in dry meadows and pastures. The root is ranked among official remedies in some parts of Europe. It has a peculiar, strong, aromatic, yet unpleasant odour, and a sweetish, pungent, biting, aromatic, bitterish taste. Its active constituents are volatile oil, and an acrid resin. It is considered diaphoretic, diuretic, and stomachic; and has been used in chronic catarrh, asthma, dropsy, amenorrhœa, &c. The dose in substance is about half a

drachm, and in infusion two drachms. The root is also used as a masticatory in toothache, as a gargle in palsy of the tongue and in collections of viscid mucus in the throat, and externally to remove freckles.

PINCKNEYA PUBENS. Michaux. A large shrub or small tree, growing in South Carolina, Georgia, and Florida, in low and moist places along the sea coast. It is closely allied, in botanical characters, to the Cinchonæ, with which it is ranked by some botanists, though it certainly does not belong to that genus as defined by De Candolle. The bark is bitter, and has been used with advantage in intermittent fever. Dr. Law, of Georgia, cured six out of seven cases in which he administered it. The dose and mode of preparation are the same with those of cinchona. The chemical composition and medical properties of this bark deserve a fuller investigation than they have yet received.

PLANTAGO MAJOR. *Plantain.* A well known perennial herb, growing in fields, by the roadsides, and in grass plats, and abounding both in Europe and this country. The leaves are saline, bitterish, and austere to the taste, the root saline and sweetish. The plant has been considered refrigerant, diuretic, deobstruent, and somewhat astringent. The ancients esteemed it highly, and employed it in visceral obstructions, hemorrhages, particularly from the lungs, consumption, dysentery, and other complaints. In modern times it has been applied to similar purposes, and the root is said to have proved useful in intermittents. At present, however, it is generally believed to be very feeble, and is little used internally. As an external application it has been recommended in ulcers of various kinds, and in indolent tumours of a scrofulous character. Among the vulgar it is still much used as a vulnerary, and as a dressing for blisters and sores. The dose of the expressed juice is from one to four fluidounces. Two ounces of the fresh root or leaves may be boiled in a pint of water and given during the day. Externally, the leaves are applied in substance or decoction. The *Plantago media*, and the *P. lancifolia* or *rib-grass*, which are also indigenous species, possess properties similar to those of the *P. major*, and may be used for the same purposes.

Under the name of *semen psyllii*, the seeds of several species of *Plantago*, growing in different parts of Europe, are sometimes kept in the shops. The best are obtained from the *Plantago Psyllium* or *fleawort*, which grows in the South of Europe and Barbary. They are small, about a line long by half a line in breadth, convex on one side, concave on the other, flea-coloured, shining, inodorous, and nearly tasteless, but very mucilaginous when chewed. They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medical properties.

PLATINUM. In 1826 Prof. Gmelin, of Tubingen, made experiments to determine the action of this metal on the economy. Within a few years Dr. Ferdinand Hoefer has investigated the same subject. The latter experimented chiefly with the bichloride, and the double chloride of platinum and sodium. They are both poisonous; the bichloride in the dose of 15 grains, the double chloride in that of 30 grains. When a concentrated solution of the bichloride is applied to the skin, it produces violent itching, followed by an eruption. Administered internally it irritates the mucous membrane of the stomach, and occasions headache. The double chloride has no action when externally applied, and, when given internally, operates on the system in a less sensible manner than the bichloride. It possesses the power of augmenting the urine. Dr. Hoefer ranks the preparations of platinum with the alteratives, by the side of those of gold, iodine, and arsenic. He considers them particularly suited to the treatment of syphilitic diseases; the bichloride to cases of long standing and inveterate, the double chloride, to those which are recent. The dose of the bichloride is from one to two grains, twice a day, given in pill. Eight grains may be made into sixteen pills, with a drachm of the extract of guaiac of the French Codex and sufficient powdered liquorice root. Of these one, two, or three may be taken morning and evening. The double chloride may be prepared for administration by dissolving five grains of the bichloride and eight of pure chloride of sodium in seven fluidounces of gum-water. This quantity may be taken by tablespoonfuls in the course of the twenty-four hours. Dr. Hoefer used for frictions on indolent ulcers, an ointment composed of sixteen grains of the bichloride, thirty-two grains of extract of belladonna, and an ounce of lard. (*Journ. de Pharm.* xxvii. 213.)

PLUMBAGO EUROPEA. *Leadwort. Dentellaria.* A perennial, herbaceous plant, growing in the South of Europe. It has an acrid taste, and, when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothache. Hence the plant derived the name of *dentelaire*, by which it is

known in France. A decoction of the root in olive oil has been highly recommended for the cure of the itch. Writers differ much in their statements in relation to the activity of the plant, some speaking of it as rubefacient, vesicatory, and caustic, and, when swallowed, as violently emetic and liable to produce dangerous irritation of the alimentary canal; while others consider it nearly inert. Perhaps the difference may be ascribed in part to the use of the plant in the recent state in one case, and dried or long kept in the other. A crystallizable, acrid principle, called *plumbagin*, has been extracted from the root by Dulong.

POLYPODIUM VULGARE. *Common Polypody.* A fern belonging both to the old and new continents, and growing in the clefts of old walls, rocks, and decayed trunks of trees. The root, which is the part considered medicinal, is rather long, about as thick as a goosequill, somewhat contorted, covered with brown, easily separable scales, furnished with slender radicles, and marked by numerous small tubercles. As found in the shops, it is sometimes destitute of the scales and radicles. Its colour is reddish-brown with a tinge of yellow, its odour disagreeably oleaginous, its taste peculiar, sweetish, somewhat bitter, and nauseous. The root of the variety growing upon the oak has been preferred, though without good reason. It was deemed purgative by the ancients, who employed it for the evacuation of bile and pituitous humours, in melancholic and maniacal cases. Modern physicians have used it in similar complaints, and as a pectoral in chronic catarrh and asthma. At present, however, it is scarcely ever employed, being considered nearly inert. It was given in doses varying from one or two drachms to an ounce, usually in connexion with cathartic medicines.

POPULUS. *Poplar.* Several trees belonging to this genus of plants have attracted some attention in a medical point of view. In most of them, the leaf buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odour, and a bitterish, balsamic, somewhat pungent taste. This is abundant in the buds of the *Populus nigra* or *black poplar* of Europe, which are officinal in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of the *P. balsamifera*, growing in the northern parts of this continent and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree, which is sometimes, though erroneously, called *tacamahac*. The virtues of the poplar buds are probably analogous to those of the turpentine and balsams. They have been used in pectoral, nephritic, and rheumatic complaints, in the form of tincture; and a liniment, made by macerating them in oil, has been applied externally in cases of local rheumatism. The *unguentum populeum* of European pharmacy is made, according to the directions of the French Codex of 1837, by bruising in a marble mortar, and boiling in 2000 parts of lard, with a gentle fire, till the moisture is dissipated, 250 parts, each, of the fresh leaves of the black poppy, deadly nightshade, henbane, and black nightshade (*Solanum nigrum*); then adding of the dried buds of the black poplar, bruised, 375 parts; digesting for 24 hours; straining with strong expression; and finally allowing the ointment to cool after defecation. This is an anodyne ointment, occasionally employed in Europe as an application in painful local affections.

The bark of some species of poplar is possessed of tonic properties, and has been used in intermittent fever with advantage. Such is the case with that of the *P. tremuloides* or *American aspen*, and of the *P. tremula* or *European aspen*. In the bark of the latter species, Braconnot found *salicin*, and another proximate crystallizable principle which he named *populin*. It is in these principles, probably, that the febrifuge properties of the bark reside. They may be obtained by precipitating a saturated decoction of the bark with solution of subacetate of lead, filtering, precipitating the excess of lead by sulphuric acid, again filtering, evaporating, adding animal charcoal towards the end of the evaporation, and filtering the liquor while hot. Salicin gradually separates, upon the cooling of the liquor, in the form of crystals. If, when this principle has ceased to crystallize, the excess of sulphuric acid in the liquid be saturated by a concentrated solution of carbonate of potassa, the populin will be precipitated. If this be pressed between folds of blotting paper, and redissolved in boiling water, it will be deposited, upon the cooling of the liquid, in the crystalline state. The leaves of the *P. tremula* also afford populin, and in larger proportion even than the bark. It is probable that both principles exist also in the bark of the *P. tremuloides*, and some other species. Salicin is described under the head of *Salix*. *Populin* is very light, of a pure white colour, and of a bitter, sweetish taste, analogous to that of liquorice. When heated it readily melts into a colourless and transparent liquid. It is soluble in 2000 parts of cold, and about 70 parts of boiling water; and is more

soluble in boiling alcohol. Acetic acid and the diluted mineral acids dissolve it, and upon the addition of an alkali, let it fall unchanged.

PORTULACA OLERACEA. *Garden Purslane.* An annual succulent plant, growing in gardens and cultivated grounds in the United States, Europe, and most other parts of the globe. It has an herbaceous, slightly saline taste, and is often used as greens, being boiled with meat, or other vegetables. It is considered a cooling diuretic, and is recommended in scorbutic diseases, and affections of the urinary passages. The seeds have been thought to be anthelmintic; but they are tasteless and inert.

POTENTILLA REPTANS. *Cinquefoil.* A perennial, creeping, European herb, with leaves which are usually quinate, and have thus given origin to the ordinary name of the plant. The root has a bitterish, styptic, slightly sweetish taste, and was formerly used in diarrhœa and other complaints for which astringents are usually prescribed.

PRUNELLA VULGARIS. *Self-heal. Heal-all.* A small perennial labiate plant, common both in Europe and the United States, growing especially by the way-sides. It is inodorous, but has an austere bitterish taste. The herb in flower was formerly used, in the state of infusion or decoction, in hemorrhages and diarrhœa, and as a gargle in sorethroat. In this country, it is not employed in regular practice.

PULMONARIA OFFICINALIS. *Lungwort.* An herbaceous perennial, indigenous in Europe, and sometimes cultivated in this country in gardens. The leaves, which are the part used, are inodorous, and have an herbaceous, somewhat mucilaginous, and feebly astringent taste. They have been considered pectoral and demulcent, and have been employed in catarrh, hæmoptysis, consumption, and other affections of the chest; but their virtues are doubtful, and they were probably applied to the treatment of pectoral complaints as much on account of the supposed resemblance of their speckled surface to that of the lungs, as from the possession of any positively useful properties.

PUMICE STONE. *Pumex.* A very light porous stone, found in the vicinity of active or extinct volcanoes, and believed to have been thrown up during their eruption. The pumice stone of commerce is said to be obtained chiefly from Lipari. It is used whole, in the manner of a file, for removing the outer surface of bodies, or for rubbing down inequalities, and, in the state of powder, for polishing glass, metals, stones, &c.; purposes to which it is adapted by the hardness of its particles.

PYRETHRUM PARTHENIUM. Willd. *Matricaria Parthenium*, Linn. *Chrysanthemum Parthenium*, Pers. *Feverfew.* A perennial herbaceous plant, about two feet high, with an erect, branching stem, pinnate leaves, oblong, obtuse, gashed, and dentate leaflets, and compound flowers borne in a corymb upon branching peduncles. It is a native of Europe, but cultivated in our herb gardens. The whole herbaceous part is used. The plant has an odour and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers, and in its medical properties. Though little employed, it is undoubtedly capable of useful application as a mild tonic.

REALGAR. This is the protosulphuret of arsenic, consisting of one eq. of arsenic 37·7, and one of sulphur 16·1=53·8. It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. Realgar is artificially made by melting arsenious acid with about half its weight of sulphur. (*Turner.*) Thus prepared, it is of a crystalline texture, of a beautiful ruby-red colour, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocent when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little arsenious acid. Realgar is used only as a pigment.

RED CHALK. *Reddle.* A mineral substance of a deep red colour, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a lively red trace when drawn over paper. It consists of clay and oxide of iron, and is intermediate between *bole* and *red ochre*, containing more oxide of iron than the former, and less than the latter. It is used for drawing lines upon wood, &c., and is sometimes made into crayons by levigating and elutriating it, then forming it into a paste with mucilage of gum Arabic, moulding this into cylinders, and drying it in the shade. It has been used internally as an absorbent and astringent.

RESEDA LUTEOLA. *Weld. Dyer's weed.* An annual European plant, natu-

ralized in the United States. It is inodorous, and has a bitter taste, which is very adhesive. In medicine it has been employed as a diaphoretic and diuretic, but is now neglected. On the continent of Europe it is much employed for dyeing yellow, and before the introduction of quercitron into England, was extensively applied to the same purpose in that country. The whole plant is used.

RHODODENDRUM CRYSTANTHUM. *Yellow-flowered Rhododendron.* This is a beautiful evergreen shrub, about a foot high, with spreading branches, and oblong, obtuse, thick leaves, narrowed towards their footstalks, reflexed at the margin, much veined, rugged and deep green upon their upper surface, ferruginous or glaucous beneath, and surrounding the branches upon strong petioles. The flowers are large, yellow, on long peduncles, and arranged in terminal umbels. The corolla is wheel-shaped, with its border divided into five roundish, spreading segments. The plant is a native of Siberia, delighting in mountainous situations, and flowering in June and July. The leaves are the part used in medicine. When fresh they have a feeble odour, said to resemble that of rhubarb. In the dried state they are inodorous, but have an austere, astringent, bitterish taste. They yield their virtues to water and alcohol.

The leaves of this species of *Rhododendron* are stimulant, narcotic, and diaphoretic, producing, when first taken, increase of heat and arterial action, subsequently a diminished frequency of the pulse, and in large doses, vomiting, purging, and delirium. They have been long employed by the natives of Siberia as a remedy in rheumatism, and their use has extended to various parts of Europe. Their action is said to be accompanied with a sensation of creeping or pricking in the affected part, which subsides in a few hours, leaving the part free from pain. They have been recommended also in gout, lues venerea, and palsy. In Siberia they are prepared by infusing two drachms of the dried leaves in about ten ounces of water, in a close earthen vessel, and keeping the liquid near the boiling point during the night. The strained liquor is taken in the morning; and a repetition of the dose three or four days successively generally effects a cure. The remedy is not used in this country.

RIGA BALSAM. *Balsamum Carpaticum.* *Balsamum Libani.* This is a product of the *Pinus Cembra*, a large tree growing in the mountainous regions and northern latitudes of Europe and Asia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin white fluid, having an odour analogous to that of juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Cronstadt in bottles. A similar product, called *Hungarian balsam*, is obtained in the same manner from the *Pinus Pumilio*, growing on the mountains of Switzerland, Austria, and Hungary. It is scarcely known in the United States.

ROTTEN STONE. *Terra cariosa.* An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-brown colour. It is obtained from Derbyshire in England, and is used for polishing metals.

SALEP. Though not directed by any of the British Colleges, nor by our national Pharmacopœia, this substance deserves a slight notice, as it is frequently mentioned by writers on the *Materia Medica*, and is occasionally to be found in the shops. The name is given to the prepared bulbs of the *Orchis mascula* and other species of the same genus, belonging to the Linnæan class and order *Gynandria Monandria*, and to the natural family of the *Orchidaceæ*. The *male orchis* is a native of Europe, the Levant, and northern Africa. Its bulbs, which are two in number, oval or roundish, internally white and spongy, are prepared by removing their epidermis, plunging them into boiling water, then stringing them together, and drying them in the sun or by the fire. By this process they acquire the appearance and consistence which distinguishes them as found in the shops. They were formerly procured exclusively from Asia Minor and Persia, but are now prepared in France and perhaps other parts of Europe.

Salep is in small, oval, irregular masses, hard, horny, semitransparent, of a yellowish colour, a feeble odour, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble, but swelling up in cold water (*bassorin*), of another in much smaller proportion, soluble in cold water, and of minute quantities of saline matters. It also occasionally contains a little starch. It is highly nutritive, and may be employed for the same purposes with tapioca, sago, &c. The reputation which it enjoyed among the ancients, and still enjoys in the East, of possessing aphrodisiac properties, is wholly without foundation.

SANDARACH. *Sandaraca.* This is a resinous substance obtained from the *Thuya articulata*, an evergreen tree growing in the North of Africa. It is in small, irregular, roundish oblong grains or tears, of a pale yellow colour, sometimes inclining to brown, more or less transparent, dry and brittle, breaking into a powder under the teeth, of a faint agreeable odour increased by warmth, and of a resinous slightly acrid taste. It melts with heat, diffusing a strong balsamic odour, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three different resins, varying in their relations to alcohol, ether, and the oil of turpentine. The *sandaracin* of Geise, which remains after sandarach has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Sandarach was formerly given internally as a medicine, and entered into the composition of various ointments and plasters. At present it is used chiefly as a varnish. It is sometimes employed as incense, and its powder is rubbed upon paper in order to prevent ink from spreading, after letters have been scratched out.

SAPONARIA OFFICINALIS. *Soapwort.* A perennial herbaceous plant, growing wild in this country, in the vicinity of cultivation, but probably introduced from Europe. It is commonly known by the vulgar name of *bouncing bet*. It is one or two feet high, with smooth, lanceolate leaves, and clusters of conspicuous whitish or slightly purplish flowers, which appear in July and August. The root and leaves are employed. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medical virtues of the plant, reside in a peculiar extractive matter, obtained from the root by Buchholz, and called by him *saponin*. This principle constitutes, according to Buchholz, 34 per cent. of the dried root, which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. *Saponin* is obtained, though not absolutely pure, by treating the watery extract with alcohol and evaporating. It is brown, somewhat translucent, hard and brittle, with a sweetish taste, followed by a sense of acrimony in the fauces. It is soluble in water and officinal alcohol, but is insoluble in anhydrous alcohol, ether, and the volatile oils. Its watery solution froths when agitated. Soapwort has been much used in Germany as a remedy in venereal and scrofulous affections, cutaneous eruptions, and visceral obstructions. It appears to act as an alterative, like sarsaparilla, to which it has been deemed superior in efficacy by some physicians. The plant is given in the forms of decoction and extract, which may be freely taken. From two to four pints of the decoction daily are recommended in lues. The inspissated juice, given in the quantity of half an ounce in the course of a day, is said by Andry generally to cure gonorrhœa in about two weeks, without any other remedy.

SARCOCOLLA. A peculiar vegetable product, exuding spontaneously from the *Penæa Sarcocolla*, *P. mucronata*, and other species of *Penæa*, small shrubs growing at the Cape of Good Hope, in Ethiopia, Arabia, &c. It is in the form of small, roundish, irregular grains, sometimes agglutinated in masses, friable, opaque or semi-transparent, of a yellowish or brownish-red colour, inodorous unless heated, when they have an agreeable smell, and of a peculiar, bitter, sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65·3 per cent. of a peculiar substance, considered by Dr. Thomson, as holding an intermediate place between gum and sugar, and called *sarcocollin*, or pure sarcocolla, 4·6 of gum, 3·3 of a gelatinous matter having some analogy with bassorin, and 26·8 of lignin, &c. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally, and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name was derived. It is at present out of use.

SASSA GUM. This name has been applied by Guibourt to a gum, occasionally brought into market from the east, and answering so exactly to Bruce's description of the product of a tree which he calls *sassa*, that there is reason to believe in their identity. According to Guibourt's description, it is in mammillary masses or in convoluted pieces resembling an ammonite, of a reddish colour, and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water, it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither like traga-

canth forming a mucilage, nor, like Bassora gum, separating into distinct flocculi. It is rendered blue by iodine.

SATUREJA HORTENSIS. *Summer Savory.* An annual labiate plant, growing spontaneously in the South of Europe, and cultivated in gardens as a culinary herb. It has an aromatic odour and taste, analogous to those of thyme, and was formerly used as a gentle carminative stimulant; but it is now only employed to give flavour to food. The *S. montana* or *winter savory*, which is also cultivated in gardens, has similar properties, and is similarly employed.

SCOLOPENDRIUM OFFICINARUM, Smith. *Asplenium Scolopendrium*, Linn. *Harts-tongue.* A fern indigenous in Europe and America. Its vulgar name was derived from the shape of its leaves, which were the part formerly used in medicine. They have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odour. They have been used as a deobstruent in visceral affections, as an astringent in hemorrhages and fluxes, and as a demulcent in pectoral complaints; but their properties are feeble, and they have been superseded by more active medicines.

SCUTELLARIA LATERIFLORA. *Scullcap.* This is an indigenous perennial herb, belonging to the Linnæan class and order *Didynamia Gymnospermia*, and to the natural order *Labiatae*. Its stem is erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale blue colour, and disposed in long, lateral, leafy racemes. The calyx has an entire margin, which, after the corolla has fallen, is closed with a helmet-shaped lid. The tube of the corolla is elongated, the upper lip concave and entire, the lower three lobed. The plant grows in moist places, by the sides of ditches and ponds, in all parts of the Union. To the senses it does not indicate, by any peculiar taste or smell, the possession of remarkable medicinal virtues. It is even destitute of the aromatic properties which are found in many of the labiate plants. When taken internally, it produces no obvious effects upon the system. Notwithstanding this apparent inertness, it obtained, at one period, extraordinary credit throughout the United States, as a preventive of hydrophobia, and was even thought to be useful in the disease itself. A strong infusion of the plant was given in the dose of a teacupful, repeated several times a day, and continued for three or four months after the bite was received; while the herb itself was applied to the wound. Strong testimony has been adduced in favour of its prophylactic powers; but it has already shared the fate, which in this case is no doubt deserved, of numerous other specifics against hydrophobia, which have been brought into temporary popularity only to be speedily abandoned. The *Scutellaria galericulata*, or common *European scullcap*, which also grows wild in this country, has a feeble, somewhat alliaceous odour, and a bitterish taste. It has been employed in intermittents, and externally in old ulcers, but is now out of use. Another indigenous species—the *S. integrifolia*, of which the *S. hyssopifolia*, Linn., is considered by some as a variety, has an intensely bitter taste, and might probably be found useful as a tonic.

SECALE CEREALE. *Rye.* Syria, Armenia, and the southern provinces of Russia, have been severally indicated by different authors as the native country of rye. The plant is now cultivated in all temperate latitudes. The *grains* consist, according to Einhof, of 24.2 per cent. of envelope, 65.6 of flour, 10.2 of water. The *flour*, according to the same chemist, consists of 61.07 per cent. of starch, 9.48 of gluten, 3.28 of albumen, 3.28 of uncrystallizable sugar, 11.09 of gum, 6.38 of vegetable fibre, besides 5.62 of loss, comprising an acid, the nature of which was not determined. Rye flour is much used, in the dry state, as an external application to erysipelatous inflammation, and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush it is an excellent laxative article of diet; and, mixed with molasses, it may be given with great advantage in hemorrhoidal affections and prolapsus ani, connected with constipation.

SEDUM ACRE. *Biting Stone-crop. Small Houseleek.* A small, perennial, succulent European plant, growing on rocks and old walls, with stems about as long as the finger, and numerous very minute leaves. It is without odour, and has a taste which at first is cooling and herbaceous, afterwards burning and durably acrid. Taken internally it vomits and purges, and applied to the skin, produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to

old ulcers, warts, and other excrescences; but the plant is at present little employed. It has recently been recommended in Germany as a remedy in epilepsy. Other species of *Sedum* are less acrid, and are even eaten as salad in some parts of Europe. Such are the *S. rupestre* and *S. album*. The *S. Telephium* was formerly employed externally to cicatrize wounds, and internally as an astringent in dysentery and hæmoptysis; and is still esteemed by the common people in France as a vulnerary.

SEMPERVIVUM TECTORUM. *Common Houseleek.* A perennial succulent European plant, growing on rocks, old walls, and the roofs of houses, and remarkable for its tenacity of life. It is occasionally cultivated in this country as an ornament to the walls of houses, or as a domestic medicine. The leaves, which are the part used, are oblong, pointed, from half an inch to two inches in length, thick, fleshy, succulent, flat on one side, somewhat convex on the other, smooth, of a light green colour, inodorous, and of a cooling, slightly saline, astringent, and sourish taste. They are employed, in the recent state and bruised, as a cooling application to burns, stings of bees, hornets, &c., ulcers, and other external affections attended with inflammation. They contain a large proportion of supermalate of lime.

SENECIO VULGARIS. *Common Groundsel.* An annual European plant, introduced into this country, and growing in cultivated grounds. The whole herb is used, and should be gathered while in flower. It has, when rubbed, a peculiar rather unpleasant odour, and a disagreeable, herbaceous, somewhat bitterish, and saline taste, followed by a sense of acrimony. It is emetic in large doses, and has been given in convulsive affections, liver complaints, spitting of blood, &c., but is now very little used. The bruised herb is sometimes applied externally to painful swellings and ulcers. The plant is employed also as food for birds, which are very fond of it. Other species of *Senecio* have also been medicinally used; and an indigenous species, the *S. aureus* or *ragwort*, is said by Schoepf to be a favourite vulnerary with the Indians.

SESQUINITRATE OF IRON, SOLUTION OF. *Liquor Ferri Sesquinitratis.* *Sesquinitrate of the Sesquioxide of Iron.* Mr. William Kerr (*Ed. Med. and Surg. Journ.*) recommends the following formula for the preparation of this solution. Take of iron wire, in pieces, *an ounce and a half*; nitric acid *three fluidounces*; muriatic acid *a fluidrachm.* Add to the iron, the nitric acid previously diluted with fifteen fluidounces of water, and set the mixture aside until the saturation of the acid with the iron is completed, which generally occupies from seven to twelve hours. Then decant the liquor from the iron remaining undissolved, and strain. Lastly, add the muriatic acid, together with sufficient water to make the whole measure thirty fluidounces. The solution, when properly prepared, is transparent, and has a beautiful dark red colour, and a very astringent but not caustic taste. If it should become turbid upon keeping, it should be rejected. The small portion of muriatic acid added is intended to preserve the solution from decomposition. The ferruginous salt present in it, is the sesquinitrate of the sesquioxide of iron, consisting of three eqs. of the acid to two of the sesquioxide.

Dr. R. J. Graves, of Dublin, (*Am. Journ. of Med. Sci.* xviii. 216, from the *Lond. Med. and Surg. Journ.*) praises this solution as a remedy in chronic diarrhœa, especially when occurring in delicate and nervous females, in which there is no thirst, redness of tongue, tenderness of the abdomen on pressure, or other indication of inflammation. According to him it acts as a tonic and astringent. By Mr. Kerr it is considered to possess also the property of diminishing the irritability of the intestinal mucous membrane. Dr. T. C. Adam, of Michigan, (*Am. Journ. of Med. Sci.* xxiv. 61,) also reports favourably of this remedy in chronic diarrhœa, considering it, like Mr. Kerr, to act as a sedative, as well as astringent. He employed it, likewise, with good effect in menorrhagia, and both internally and by injection in leucorrhœa, when occurring in pale, exsanguine, and feeble subjects. The dose, according to Dr. Graves, is seven or eight drops, gradually increased to fifteen, sufficiently diluted, in the course of the day. Dr. Adam, however, gave it in doses of ten drops, two, three, or four times a day, and sometimes increased it to twenty-five drops. As an injection he employed it sufficiently diluted to cause only a slight heat and smarting in the vagina.

SIENNA. *Terra di Sienna.* An argillaceous mineral, compact, of a fine texture, very light, smooth and glossy, of a yellowish-brown or coffee-colour, leaving a dull orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown colour, and is then called *burnt sienna*. In both the raw and burnt

states it is used for painting. The best sienna is brought from Italy, but an inferior kind is found in England.

SILENE VIRGINICA. *Catchfly. Wild Pink.* An indigenous perennial plant, growing in Western Virginia and Carolina, and in the states beyond the Alleghany mountains. Dr. Barton, in his "Collections," states that a decoction of the roots is said to be efficacious as an anthelmintic. We are told that it is considered poisonous by some of the Indians. The *S. Pennsylvanica*, which grows in the Eastern section of the Union from New York to Virginia, probably possesses similar properties.

SISYMBRIUM OFFICINALE, Scopoli. *Erysimum officinale*, Linn. *Hedge Mustard.* A small annual plant, growing both in the United States and Europe, along the roadsides, by walls and hedges, and on heaps of rubbish. It has an herbaceous somewhat acrid taste, which is strongest in the tops and flower-spikes, and resembles that of mustard, though much weaker. The seeds have considerable pungency. The herb is said to be diuretic and expectorant, and has been recommended in chronic coughs, hoarseness, and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. The *Sisymbrium Sophia* or *flix weed* is also among the plants formerly considered officinal. It is of a pungent odour when rubbed, and of an acrid biting taste. The herb has been used externally in indolent ulcers, and the seeds internally in worms, calculous complaints, &c.

SIUM NODIFLORUM. *Water-parsnip.* A perennial, umbelliferous, aquatic European plant, growing also in the Southern section of the United States, where it is supposed to have been introduced. It is commonly considered poisonous; but the expressed juice given by Withering in the dose of three or four ounces every morning, was not found to affect the head, stomach, or bowels. He found it, in this quantity, very advantageous in obstinate cutaneous diseases; and the plant has been usefully employed by others in similar complaints, and in scrofulous swellings of the lymphatic glands. It is considered diuretic. The *S. latifolium*, which grows in Europe and the United States, and is the common water-parsnip of this country, is positively asserted to be poisonous; and madness and even death are said to have followed the use of the root. The *S. Sisarum* or *skirret*, a plant of Chinese origin, cultivated in Europe, has a sweetish, somewhat aromatic root, which is employed as food in the form of salad, and is supposed to be a useful diet in complaints of the chest.

SMALT. *Azure.* When the impure oxide of cobalt, obtained by roasting the native arseniuret of that metal, is heated with sand and potassa, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, receives the name of smalt. It is used chiefly in painting.

SOLUTION OF HYDRIODATE OF ARSENIC AND MERCURY. *Liquor Hydriodatis Arsenici et Hydrargyri. Liquor Hydrargyri et Arsenici Iodidi.* This combination was introduced to the notice of the medical profession in 1839, by Mr. Donovan of Dublin, as a therapeutic agent combining the medical virtues of its three ingredients. At present he prepares it by the following corrected formula:—Triturate 6·08 grains of finely levigated metallic arsenic, 14·82 grains of mercury, and 49 grains of iodine with a fluidrachm of alcohol, until the mass becomes dry, and from being deep brown has become pale red. Add eight fluidounces of distilled water, and, after trituration for a few moments, transfer the whole to a flask, add half a drachm of hydriodic acid, prepared by the oxidation of two grains of iodine, and boil for a few moments. When the solution is cold, if it should measure less than eight fluidounces, add sufficient distilled water to make it fill exactly that measure. Lastly filter.

This solution has a pale yellow colour, and a slightly styptic taste. Its sp. gr. is 1·02. It is incompatible with laudanum, and the sulphate, muriate, and acetate of morphia. The iodides of arsenic and mercury, formed by trituration as the first step of the process, are assumed by Mr. Donovan to become, by solution, hydriodates severally of arsenious acid (white oxide of arsenic), and of deutoxide of mercury (peroxide or red precipitate); and he has taken the solid materials and water in such proportions as that each fluidrachm of the solution, on this theory of change, shall contain an eighth of a grain of arsenious acid, a fourth of a grain of deutoxide of mercury, and about three-fourths of a grain of iodine in the state of hydriodic acid. Those who consult Mr. Donovan's first paper on this solution (*Dublin Med. Journ. for Nov. 1839*) will not understand it, unless they are aware that he means by protoxide of arsenic, arsenious acid (in composition a *sesquioxide*); and by protoxide of mercury, deutoxide of mercury or red precipitate. These corrections in his nomen-

clature he admits to be necessary in his paper of Nov. 1842, in which he states that he used the erroneous terms through inadvertence. In this preparation the iodide of arsenic present is the sesquiodide, and the iodide of mercury, the red or biniodide. If it be assumed that these iodides are capable of uniting into a double iodide, the proportion will be one eq. of the sesquiodide 454.3 to one of the biniodide 454.6. On the theory of their conversion into hydriodates by solution, five eqs. of water 45 will be required, three for the arsenical sesquioxide, and two for the mercurial biniodide; and the result will be one eq. of arsenious acid 99.4, one of deutoxide of mercury 218, and five of hydriodic acid 636.5, the latter containing five eqs. of iodine 631.5. The solution here supposed would contain about two and one-fifth times as much deutoxide of mercury as of arsenious acid, instead of only twice as much, as in Mr. Donovan's formula. If his formula had been made thus, the quantity of the deutoxide associated with an eighth of a grain of the arsenious acid, would have been increased only a fortieth of a grain above the quantity intended by him to be present in a fluidrachm of the solution; and, while this increase of the mercurial oxide would be immaterial, the advantage would have been gained of having the two iodides present in equivalent proportions.

Medical Properties. This preparation has been found decidedly useful as an alterative in the treatment of various diseases of the skin, such as the different forms of psoriasis, impetigo, porrigo, lepra, pityriasis, lupus, and venereal eruptions, both papular and scaly. In support of its efficacy in these affections, Mr. Donovan has adduced the testimony of a number of respectable practitioners, of Dublin and elsewhere, who have communicated to him the results of their experience. The disease in some of the cases cured had existed for a number of years. Dr. E. I. Taylor, of New York, has employed it in a number of cutaneous diseases, and finds that it produces more marked and prompt effects than the remedies usually resorted to in the treatment of lupus, rupia, psoriasis, and secondary venereal. (*Am. Journ. of Med. Sci. N. S. v. 319.*) In two cases of uterine disease, characterized by patency of the os uteri and vascular turgescence of the cervix, and attended with lumbar and pelvic pains, Dr. Kirby, of Dublin, afforded relief by the use of the solution. The dose is twenty minims three times a day given preferably in distilled water. This dose contains a twenty-fourth of a grain of arsenious acid, a twelfth of a grain of deutoxide of mercury, and about a quarter of a grain of iodine. Mr. Donovan originally proposed thirty minims as the dose; but many patients cannot bear this quantity. Dr. Taylor never exceeded five drops, equal to four minims, three times a day. Sometimes the medicine confines the bowels, deranges the stomach, and produces headache, giddiness, and confusion of mind. When these effects are produced, it must be laid aside and a purgative administered. After an interval varying from ten days to three weeks, it may be resumed, but in a smaller dose. The treatment often requires to be persevered in for several months. Sometimes the medicine produces moderate salivation. By some practitioners, the solution, diluted with an equal bulk of water, was used with advantage as an external application to the ulcers or eruptions, at the same time that the medicine was given internally. This preparation is deserving of trial by American practitioners in the obstinate diseases to which it is considered to be applicable. Its use is extending in Europe, and the evidence in its favour is, thus far, satisfactory. For further information the reader is referred to the three papers of Mr. Donovan, contained in the *Dublin Journal of Med. Science*, for Nov. 1839, Sept. 1840, and Nov. 1842. It is the paper of the latter date, that contains his corrected formula, which is given in the beginning of this article.

SOOT. Fuligo Ligni. This well known substance has a peculiar smell, and a bitter, empyreumatic, and disagreeable taste. Its composition is very complex. Reduced to powder and treated with water, it affords an infusion of a deep yellow or brown colour, the colour being deeper if heat be employed. The insoluble portion amounts to about forty-four per cent. The soluble part consists chiefly, according to Berzelius, of a pyrogenous resin united with acetic acid, called *acid pyretin*, and saturated with potassa, lime, and magnesia. It also contains sulphate of lime, chloride of potassium, acetate of ammonia, and traces of nitric acid. If the solution be evaporated to dryness, it furnishes a black extract. This forms with water a blackish-brown solution, which, when treated with any free acid, except the acetic, lets fall the acid pyretin, in the form of a black mass, resembling pitch; while the acid employed remains in solution with the bases previously in combination with the pyretin. Braconnot thought he had discovered in the pyretin a peculiar principle, to which he gave the name of *asbolin*; but Berzelius thinks he was mistaken. Besides these substances, Braconnot ascertained the existence in soot of an azotized extractive matter to the

amount of twenty per cent. This matter when submitted to dry distillation, afforded a considerable portion of pyrogenous oil. The soot itself, when subjected to a similar distillation, furnished one-fifth of its weight of empyreumatic oil. To the above ingredients of soot, must be added creasote, which was not discovered at the date of the researches of Berzelius and Braconnot, and to the presence of which soot is supposed to owe its medicinal properties.

Soot was formerly official with the Edinburgh College, and the Scotch physicians were in the habit of frequently prescribing it as a tonic and antispasmodic in the form of tincture. It went very much out of use in regular practice; and it is only within a few years, that its employment has been revived on account of its containing creasote. At present it is chiefly used as an external remedy in the form of decoction or ointment. In the *Revue Méd.* for June, 1834, M. Blaud details a number of cases of various affections, such as obstinate tetter, porrigo favosa, psora, fistula, cancerous and venereal ulcers, chronic irritations of the lining membrane of the mouth, exudations from the mucous membrane of the nose, herpetic eruptions of the genital organs, and pruritus of the vulva, in which the use of soot effected a cure. The *decoction* is made by adding two handfuls of soot to a pint of water, boiling for half an hour, and filtering. It is applied as a lotion to the affected parts; or injected into the fistulæ, several times a day, and, in the intervals, the part, if accessible, is dressed with an *ointment*, made by rubbing up a drachm of finely powdered soot with an ounce of lard. In cases of porrigo, the crusts must be removed by poultices, before the soot is applied. In scrofulous ophthalmia, M. Caron Duvillards and M. Baudelocque have found a collyrium, made according to the following formula, very useful. Dissolve two ounces of soot in boiling water, filter the solution, and evaporate it to dryness. Dissolve the dry residue, with the assistance of heat, in strong white wine vinegar, and add extract of roses in the proportion of twenty-four grains to twelve fluid-ounces of the liquid. It is prepared for use by adding a few drops of the liquid to a glass of water. (*Bull. Gén. de Therapeutique, Mars 1834.*) This formula is not very satisfactory, as it does not indicate the proportions of water and vinegar to be employed. In a case of severe and extensive burn, in which, after the separation of sloughs, the patient began to sink from the profuse discharge, Dr. Ebers, of Bordeaux, found advantage from the application, to the granulating surface, of lint soaked in a decoction of soot. It acted by reducing the discharge in a surprising manner, by promoting cicatrization.

We are informed by Dr. Hewson, of this city, that he has found an infusion of soot an efficacious remedy, employed by injection, in cases of ascarides. In one case, of long standing in an adult, in which a number of remedies had been tried unsuccessfully, injections of soot daily, persevered in for two weeks, effected a complete cure. The injection was made by adding a cupful of soot to a pint of boiling water, and straining the solution. An *infusion of hickory ashes and soot* has formed, for some time past, a popular remedy for dyspepsia. It is made by infusing a pint of clean hickory ashes and a gill of soot in half a gallon of boiling water, allowing the liquor to stand for twenty-four hours, and then decanting. Of this a small wineglassful is to be taken three or four times a day. No doubt this infusion has been useful in acidity of stomach; but its indiscriminate use in all gastric affections popularly confounded under the name of dyspepsia, is calculated to do much harm.

Soot is employed in the arts as a colouring matter. Meat which has been allowed to remain from half an hour to an hour in an infusion of one part of soot to six parts of cold water, keeps like smoked meat. From this fact it is evident that soot is a good antiseptic.

SPANISH BROWN. A brownish-red ochre, much used in painting.

SPARTIUM JUNCEUM. *Spanish Broom.* A small shrub, indigenous in the South of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odour. The seeds are in moderate doses diuretic and tonic, in large doses emetic and cathartic, and have been used advantageously in dropsy. The dose is from ten to fifteen grains three times a day. They may also be given in tincture.

SULPHATE OF ALUMINA. *Aluminæ Sulphas.* The salts of alumina have been ascertained by M. Gannal to be powerful preservatives of animal matter. Among these the sulphate is to be preferred on account of its easy preparation and moderate price. It may be made by saturating dilute sulphuric acid with hydrated alumina, and evaporating. A solution of this salt was found by M. Gannal to be very effectual in preserving bodies for dissection, when injected into the bloodvessels. In the summer season the bodies were preserved fresh for twenty days or more; in the winter,

for three months. For use in the winter, a quantity of solution, sufficient for injecting one body, may be made by adding a pound, avoirdupois, of the salt to a quart of water; for use in hot weather, the solution must be made stronger. The *acetate of alumina* and the *chloride of aluminium* (muriate of alumina) possess the same preservative power.

SULPHOCYANURET OF POTASSIUM. *Potassii Sulphocyanuretum.* This salt is prepared by fusing in an iron vessel, at a low red heat, a mixture of two parts of dried ferrocyanuret of potassium, and one part of flowers of sulphur. The mass, when cold, is dissolved in boiling water, and, to decompose some sulphocyanuret of iron, the solution is treated with carbonate of potassa, which throws down the iron as a carbonate, and gives rise to the formation of a fresh portion of sulphocyanuret of potassium. The whole is then boiled for a quarter of an hour, filtered to separate the precipitated iron, and evaporated that crystals may form. These are purified from carbonate of potassa, by being dissolved in alcohol, which takes up the sulphocyanuret and leaves the carbonate. The alcoholic solution is then allowed to crystallize. Sulphocyanuret of potassium is in long, striated, anhydrous prisms, deliquescent in a moist atmosphere, very soluble in alcohol, and having a cooling, somewhat biting taste. It has been proposed as a medicine by Sæmmering, as a substitute for hydrocyanic acid and cyanuret of potassium, on the ground that it possesses the same therapeutic properties, without their inconveniences.

SWIETENIA FEBRIFUGA. A large tree growing in the East Indies. The bark is the portion medicinally employed. It is smooth and red internally, rough and gray on the outer surface, of a feeble aromatic odour, and an astringent bitter taste. Water extracts its virtues by infusion or decoction. It is said to have been much used in India as a substitute for Peruvian bark, to which it is somewhat analogous in medical properties, though it contains neither cinchonia nor quinia. The dose of the powder is from thirty grains to half a drachm. The watery extract has the virtues of the bark.

The *Swietenia Mahagoni* or *Mahogany tree*, which grows in the West Indies and other parts of tropical America, has also a bitter astringent bark, which resembles that of the *S. febrifuga* in virtues as well as in sensible properties. The wood of this tree is the mahogany so much used in ornamental wood-work.

SYMPHYTUM OFFICINALE. *Comfrey.* A perennial European plant, cultivated in our gardens for medical use. Its root, which is the part used, is spindle-shaped, branched, often more than an inch thick and a foot long, externally smooth and blackish, internally white, fleshy, and juicy. By drying, it becomes wrinkled, of a firm horny consistence, and of a dark colour within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. Among its constituents are mucilage in great abundance, and a small quantity of tannin. It was formerly highly esteemed as a vulnerary, but has lost its credit in this respect. Its virtues are chiefly those of a demulcent, and it may be advantageously used for all the purposes to which the marshmallow is applied. It is a very common ingredient in the domestic cough mixtures employed in chronic catarrhs, consumption, and other pectoral affections. The most convenient form of administration is that of decoction, which may be made either from the fresh or dried root. According to Lewis, comfrey root yields to water a larger proportion of mucilage than the root of the *Althæa*.

SYRINGA VULGARIS. *Common Lilac.* The leaves and fruit of this common garden plant have a bitter and somewhat acrid taste, and have been used as a tonic and febrifuge. In some parts of France, they are said to be employed habitually by the country people in the cure of intermittent fever; and they were recommended by Cruveilhier in the treatment of that complaint. The fruit was examined by MM. Petroz and Robinet, who found a sweet and a bitter principle. The latter has been obtained pure by M. Meillet, who has given it the name of *lilacin*. The green capsules, which yield it in largest proportion, are boiled in water, the decoction is concentrated, subacetate of lead is added, the liquor is evaporated to the consistence of syrup, magnesia is added in excess, and the whole is evaporated to dryness. The residuum is powdered, digested in water at 90° or 100°, and then treated with boiling alcohol, and animal charcoal. The alcoholic solution, being filtered and concentrated, yields lilacin upon cooling. This principle, though not alkaline, is thought by M. Meillet to exist in the fruit combined with malic acid. It is crystallizable, bitter, and insoluble in water. (*Am. Journ. of Pharm.* xiv. p. 139, from *Journ. de Pharm.*)

TACAMAHAC. *Tacamahaca.* The resinous substance commonly known by this name, is supposed to be derived from the *Fagara octandra* of Linn. (*Elaphrium tomentosum*, Jacq., *Amyris tomentosum*, Spreng.), a tree of considerable size, growing in the

island of Curaçoa, and in Venezuela. The juice exudes spontaneously, and hardens on exposure. As brought into the market, it is in irregularly shaped pieces of various sizes, some not larger than a mustard seed, others as much as an inch or two inches in diameter. The colour is usually light-yellowish or reddish-brown; but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale-yellow powder. Their odour is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat they melt and exhale a stronger odour. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

Another variety is obtained from the East Indies, and called *tacamahaca orientale*, or *tacamahaca in testis*. It is supposed to be derived from the *Calophyllum Inophyllum*, and comes into the market in gourdshells covered with rush leaves. It is of a pale yellow colour inclining to green, slightly translucent, soft and adhesive, of an agreeable odour, and an aromatic bitterish taste. It is at present very rare in commerce.

Guibourt describes several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark-green resin, said to be procured from the *Calophyllum Tacamahaca* of Willd., a tree growing in the islands of Bourbon and Madagascar.

Tacamahac was formerly highly esteemed as an internal remedy, but is now employed medicinally only in the composition of ointments and plasters, and little even for this purpose. Its properties are analogous to those of the turpentine. It is sometimes used as incense.

TANNATE OF LEAD. This is obtained by precipitating a concentrated infusion of oak bark with acetate of lead, added drop by drop. It has been used as an external application with success by Dr. Fantonetti in two cases of white swelling of the knee joint. He employed it at first mixed with a third of its weight of lard, and afterwards pure, the fresh precipitate admitting of application as an ointment. Autenrieth recommends it as a dressing to gangrenous sores, and Dr. Tott for the same purpose. With this intention, the precipitate, either uncombined, or mixed, in its dry state, with simple ointment in the proportion of two drachms to the ounce, may be spread on linen and applied to the sore. The preparation here referred to is in composition a bitannate. Other tannates of lead exist.

TEA. The plant which furnishes tea—*Thea Chinensis*—is an evergreen shrub, belonging to the class and order Monadelphia Polyandria of the Sexual system (Polyandria Monogynia, Linn.), and to the natural order Ternströmiaceæ. It is usually from four to eight feet high, though capable, in a favourable situation, of attaining the height of thirty feet. It has numerous alternate branches, furnished with elliptical oblong or lanceolate, pointed leaves, which are serrate except at the base, smooth on both sides, green, shining, marked with one rib and many transverse veins, and supported alternately upon short footstalks. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary, or supported two or three together at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-celled and three-seeded capsule. It has not been certainly determined whether more than one species of the tea-plant exists. Linnæus admitted two species—the *T. Bohea* and the *T. viridis*—differing in the number of their petals; but this ground of distinction is untenable, as the petals are known to vary very much in the same plant. Hayne makes three species—the *T. stricta*, *T. Bohea*, and *T. viridis*, which are distinguished severally by the shape of their leaves and fruit, and the direction of the footstalk. De Candolle admits but one species, with two varieties—the *viridis* or green tea, with "lanceolate flat leaves, three times as long as they are broad," and the *Bohea*, with "elliptical oblong, subrugose leaves, twice as long as broad." Lindley recognises the two Linnean species, distinguishing them by the leaves, which, in the *T. viridis*, are acuminate and emarginate at the apex, and in the *T. Bohea* are smaller, flatter, darker green, with small serratures, and terminate gradually in a point, but are not at all acuminate or emarginate. (*Flora Medica*, 120.)

The tea-plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. In Japan it forms hedgerows around the rice and cornfields; in China, whence immense quantities of tea are exported, whole fields

are devoted to its culture. It is propagated from the seeds, which are planted in holes at certain distances apart, six or eight seeds being placed in each hole, in order to ensure the growth of one. In three years the plant yields leaves for collection, and in six years attains the height of a man. When from seven to ten years old, it is cut down, in order that the numerous shoots which issue from the stump may afford a large product of leaves. These are picked separately by the hand. Three harvests, according to Kœmpfer, are usually made during the year, the first at the end of February, the second at the beginning of April, and the third in June. As the youngest leaves are the best, the product of the first collection is most valuable, while that of the third, consisting of the oldest leaves, is comparatively little esteemed. Sometimes only one or two harvests are made; but care is always taken to assort the leaves according to their age; and thus originate numerous commercial varieties of tea. The character of the plant, dependent upon the soil, situation, climate, and culture, has also a great influence upon the value of the leaves. It is said that the best tea is procured from the shrubs which grow upon the sides of steep hills with a southern exposure. Though the plant grows both about Peking in the North, and Canton in the South of China, it is said to attain greater perfection in the intermediate country, in the neighbourhood of Nankin for instance, where the climate is neither so cold as in the first mentioned vicinity, nor so hot as in the second. Some of the commercial varieties have their origin in this cause; and it is not impossible, though the fact has not been ascertained, that difference in species may be another source of diversity in the product. After having been gathered, the leaves are dried by artificial heat in shallow iron pans, from which they are removed while still hot, and rolled with the fingers, or in the palm of the hand, so as to be brought into the form in which they are found in commerce. It is stated that the odour of the tea leaves themselves is very slight; and that it is customary to mix with them the leaves of certain aromatic plants, such as the *Olea fragrans* and *Camellia Sasanqua*, in order to render them pleasant to the smell. It is obvious that the nature of the addition will affect to a certain extent the quality of the tea, and thus still further increase the diversity arising from the age of the leaf and the character of the plant.

Tea is brought to this country from the port of Canton. Numerous varieties exist in commerce, differing in the shape communicated by rolling, in colour, in flavour, or in strength; but they may all be arranged in the two divisions of *green* and *black teas*, which, at least in their extremes, differ so much in properties, that it is difficult to conceive that they are derived from the same species.

Properties. *Green tea* is characterized by a dark-green colour, sometimes inclining more or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odour, and an astringent, slightly pungent, and agreeably bitterish taste. Its infusion has a pale greenish-yellow colour, with the odour and taste of the leaves. *Black tea* is distinguished by a dark brown colour. It is usually less firmly rolled, and lighter than the green, and contains the petioles of the plant mingled with the leaves. Its odour is fainter and of a somewhat different character, though still fragrant. Its taste, like that of green tea, is astringent and bitterish; but it is less pungent, and to most persons less agreeable. To hot water it imparts a brown colour, with its sensible properties of taste and smell. These vary exceedingly in strength in the different varieties; and some black teas are almost wholly destitute of aromatic or agreeable flavour.

According to the analysis of G. J. Mulder, which is the most recent, 100 parts of green Chinese tea afforded 0.79 of volatile oil, 2.22 of chlorophylle, 0.28 of wax, 2.22 of resin, 8.56 of gum, 17.80 of tannic acid, 0.43 of thein, 22.80 of extractive, traces of apotheme, 23.60 of muriatic extract, 3.00 of albumen, 17.68 of lignin, and 5.56 of salts. The muriatic extract was the matter taken up by diluted muriatic acid from tea previously exhausted successively by ether, alcohol, and water, and consisted of artificial tannin. The same chemist obtained from 100 parts of black Chinese tea 0.60 of volatile oil, 1.84 of chlorophylle, 3.64 of resin, 7.28 of gum, 12.88 of tannic acid, 0.46 of thein, 19.88 of extractive, 1.48 of apotheme, 19.12 of muriatic extract, 2.80 of albumen, 23.32 of lignin, and 5.24 of salts. (*Annal. der Pharm.* xxviii. 317.) But there is no doubt that the different specimens of each of these varieties of tea often vary exceedingly in the proportion of their constituents. The volatile oil is the principle upon which the effects of tea upon the nervous system chiefly if not exclusively depend. Hence old teas are less energetic than those recently imported; and it is said that the fresh leaves have often produced dangerous effects in China. Nevertheless, the tannic acid is not without influence upon the system; and it is not improbable that both the extractive and thein contribute to the peculiar influences of this valuable product. Of these active ingredients, the volatile oil, tannic acid, and extractive, are found most

largely, according to the analysis of Mulder, in the green tea. *Thein* is a crystallizable principle discovered by Oudry. It was afterwards proved by Jobst to have the same composition as caffeine, and is now generally considered as in all respects identical with that principle. (See *Coffee*.) Jobst obtained it by boiling tea repeatedly with water, filtering and concentrating the decoction, adding acetate of lead so long as it occasioned a precipitate, again filtering, precipitating the lead by sulphuretted hydrogen, and lastly, filtering and evaporating. The *thein* crystallized in small, delicate, acicular crystals, which were purified by a new crystallization from water, alcohol, or ether. According to Mulder, *thein* exists in tea combined with tannic acid, and is obtained in the simplest manner from the decoction, by precipitating the acid with magnesia or lime, evaporating the liquid, and exhausting the residue with ether, which yields the principle quite pure. (*Annal. der Pharm.* xxvii. 319.) *Thein* has a feebly bitter taste; in the state of crystals, is dissolved by 93 parts of water, 158 of alcohol, and 298 of ether; melts at about 350° F., and at 723° sublimes in white vapours which condense in minute needles. From its watery solution scarcely any reagent precipitates it. Infusion of galls causes a deposit of tannate of *thein*, which is again, however, dissolved by heating the water. (*Ibid.*)

Medical Properties and Uses. Tea is astringent and gently excitant, and in its finer varieties exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise when taken in unusual quantities, or by those unaccustomed to its use. Its properties, however, are not of so decided a character as to render it capable of very extensive application as a medicine; and its almost exclusive use, as every one knows, is as a grateful beverage at the evening and morning meals. Taken moderately, and by healthy individuals, it may be considered as perfectly harmless; but long continued, in excessive quantity, it is capable of inducing unpleasant nervous and dyspeptic symptoms, the necessary consequences of over excitement of the brain and stomach. Green tea is decidedly more injurious in these respects than black, and should be avoided by dyspeptic individuals, and by those whose nervous systems are peculiarly excitable. As a medicine, tea may sometimes be given advantageously in diarrhoea; and a strong infusion will often be found to relieve nervous headache. For the latter purpose green tea should be preferred. The mode of preparing tea for use is too well known to require description. An extract is made from it in China, which is said to be useful in fevers.

TEUCRIUM CHAMÆDRYS. *Germander. Chamædrys.* A small, didynamous, labiate, perennial, European plant, the leaves and tops of which have an agreeable aromatic odour, diminished by drying, and a bitter, somewhat astringent, aromatic, durable taste. They have been employed as a mild corroborant, in uterine, rheumatic, gouty, and scrofulous affections, and intermittent fevers; but are at present little used, and never in this country. Germander was an ingredient in the *Portland powder*, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of the *Aristolochia rotunda* and *Gentiana lutea*, of the tops and leaves of the *Teucrium Chamædrys* and *Erythraea Centaurium*, and of the leaves of the *Ajuga Chamæpytis* or *ground pine*. The dose was a drachm taken every morning before breakfast, and continued for three months, then two scruples for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (*Parr.*)

Two other species of *Teucrium* have been used in medicine—the *T. Marum*, *cat thyme*, or *Syrian herb mastich*, which is a native of the South of Europe, and the *T. Scordium*, or *water germander*, which grows in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been highly recommended in hysteria, amenorrhœa, and cases of nervous debility; the latter has the odour of garlic, and a bitter somewhat pungent taste, and was formerly highly esteemed as a corroborant in low forms of disease; but neither of them is now much employed. The *T. Marum* is errhine, and was formerly an ingredient in the *Pulvis Asuri Compositus*. The dose of either of the three species of *Teucrium* is about half a drachm.

THUJA OCCIDENTALIS. *Arbor Vitæ.* An indigenous evergreen tree, growing wild from Canada to Carolina, and cultivated for ornament in gardens. The leaves, or small twigs invested with the leaves, are the part used. They have an agreeable balsamic odour, especially when rubbed, and a strong, balsamic, camphorous, bitter taste. In the state of decoction, they have been used in intermittent fever, and, according to Schoepf, in coughs, fevers, scurvy, and rheumatism. Made into an ointment with lard or other animal fat, they are said to form a useful local application in rheu-

matic complaints. The distilled water is praised by Boerhaave as a remedy in dropsy. (*Schoepf.*) A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in worms.

THYMUS VULGARIS. *Thyme.* A small well known undershrub, indigenous in the South of Europe, and with us cultivated in gardens. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odour, which is not lost by drying, and a pungent, aromatic, camphorous taste. Its active constituent is a volatile oil, which may be separated by distillation. Oil of thyme (*oleum thymi*) is, when fresh, of a pale yellow or greenish colour, but as found in the shops is often brown. Its sp.gr. is 0.905. The plant has the aromatic properties of sage, lavender, &c., and may be used for the same purposes. It is, however, more employed in cookery than in medicine. The *T. Serpillum*, or *wild thyme* of Europe, is analogous in properties to the garden thyme. Both are occasionally used in baths, fomentations, and poultices, along with other aromatic herbs.

TONKA BEAN. The seed of the *Dipterix odorata* of Willd., the *Coumarouna odorata* of Aublet, a large tree growing in Guiana. The fruit is an oblong-ovate pod, enclosing a single seed, from an inch to an inch and a half long, from two to four lines broad, usually somewhat compressed, with a dark-brown, wrinkled, shining, thin, and brittle skin, and a light-brown, oily kernel. The bean has a strong, agreeable, aromatic odour, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, analogous to the volatile oils and camphor, and called *coumarin* by Guibourt. This substance is sometimes found in a crystalline state, between the two lobes of the kernel. The tonka bean is used to flavour snuff, being either mixed with it in the state of powder, or put entire into the snuff-box.

TRIGONELLA FÆNUMGRÆCUM. *Fenugreek.* An annual plant growing spontaneously in different parts of the South of Europe, and cultivated in France and Germany for the sake of its seeds. These are one or two lines in length, oblong cylindrical, somewhat compressed, obliquely truncated at each extremity, brownish-yellow externally, yellow internally, and marked with an oblique furrow running half their length. They have a strong peculiar odour, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oil, mucilage, bitter extractive, and a yellow colouring substance. An ounce of the seeds boiled in a pint of water renders it thick and slimy. They give out the whole of their distinguishing odour and taste to alcohol. Their virtues depend chiefly upon their oil and mucilage. On the continent of Europe they are employed in the preparation of emollient cataplasms and enemata, and enter into the composition of some officinal ointments and plasters. They are never used internally.

TRIPOLI. *Terra Tripolitana.* An earthy mineral, of a whitish, yellowish, or pale straw colour, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting the aspect of argillaceous earth, though differing from clay by the roughness and hardness of its particles, and by not forming a paste with water. The *Venice tripoli* is said to come from the island of Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals.

TRITICUM REPENS. *Couch-grass. Dog-grass. Quickens.* A perennial European plant, very common in gardens and cultivated grounds, where it is considered a troublesome weed. The root, which is the part medically used, is horizontal, creeping, jointed, about as thick as a straw or thicker, inodorous, and of an agreeable, sweetish, slightly pungent taste. It is used in some parts of Europe, in the form of decoction, as a slightly aperient and nutritive drink. Great quantities of it are said to be consumed in the hospitals of Paris. The decoction, in consequence of the sugar which it contains, is susceptible of the vinous fermentation.

TUTTY. *Tutia. Impure Oxide of Zinc.* This oxide is formed during the smelting of lead ores containing zinc. It is deposited in the chimneys of the furnaces, in the form of incrustations, moderately hard and heavy, and studded over with small protuberances, of a brownish colour on the outside, and yellowish within. As it occurs in commerce, the pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious substance is sold for tutty, consisting of a mixture of blue clay and copper filings, made into a paste with water, and dried on an iron rod. It is distinguished from the genuine tutty by its diffusing in water and exhaling an earthy smell, and by its greater friability.

Tutty is used as an external application only, as an exsiccant in excoriations. To fit it for medical use it must be reduced to fine powder, which is dusted on the affect

ed part, or applied in the form of ointment. It has been very properly dismissed from the Edinburgh officinal catalogue, its use being superseded by that of the pure oxide.

UMBER. *Terra Umbria.* A mineral of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale brown colour, which changes to a peculiar beautiful deep brown by heat. According to Klaproth, it contains 13 parts of silica, 5 of alumina, 48 of oxide of iron, 20 of manganese, and 14 of water in 100. *Burnt umber*, as well as the mineral in its unaltered state, is used in painting. The umber of commerce is said to be brought chiefly from the island of Cyprus.

URTICA DIOICA. *Common nettle.* A well known perennial herbaceous plant, growing both in Europe and the United States, by the roadsides, in hedges, and gardens. The leaves, seeds, and roots, were formerly officinal. They were deemed diuretic and astringent, and were employed in nephritic complaints, hemorrhages, consumption, jaundice, worms, &c. The young shoots are boiled and eaten by the common people as a remedy in scurvy; and the fresh plant is sometimes used to excite external irritation in cases of torpor and local palsy, the part being beaten with it till the requisite degree of action is produced. The *U. urens* or *dwarf nettle*, which is an annual plant, and smaller than the former species, has similar properties, and is used for the same purposes. This species also grows wild both in America and Europe. The two plants were formerly distinguished by the names of *urtica major*, applied to the *U. dioica*, and of *urtica minor* applied to the *U. urens*.

VANILLA. This is the fruit of the *Vanilla aromatica* of Schwartz, the *Epidendrum Vanilla* of Linn., a climbing plant, growing in the West Indies, Mexico, and South America. It is said also to be cultivated in the Isle of France. The pods are collected before they are quite ripe, dried in the shade, covered over with a coat of fixed oil, and then tied in bundles, which are surrounded with sheet lead, or enclosed in small metallic boxes, and sent into the market. Several varieties of vanilla exist in commerce. The most valuable, called *ley* by the Spaniards, consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines thick, nearly straight, narrowing towards the extremities, bent at the base, shining and dark-brown externally, wrinkled longitudinally, soft and flexible, and containing within their tough shell, a soft black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong, agreeable odour, bearing some resemblance to that of balsam of Peru, and a warm, aromatic, sweetish taste. The interior pulpy portion is most aromatic. Another variety, called *simarona* by the Spaniards, is smaller, of a lighter colour, and less aromatic. A third variety is the *promprona* of the Spaniards. In this, the pods are from five to seven inches long, from six to nine lines broad, almost always open, brown, soft, viscid, and of a strong odour, but less pleasant than that of the *ley*, to which it is considered inferior. According to Buchholz, vanilla does not yield volatile oil when distilled with water. It is employed to flavour chocolate, ice-cream, &c., and as a perfume.

VENETIAN RED. *Bolus Veneta.* A dull red ochrey substance used in painting.

VERBENA OFFICINALIS. *Vervain.* This is a common European weed, growing on the roadsides, in the vicinity of towns and villages. Its sensible properties do not indicate the possession of medical virtues; as it is nearly inodorous, and has only a slightly astringent bitterish taste. By the ancients it was highly esteemed both as a remedy in disease, and as a sacred plant employed in the performance of religious rites. In modern times, superstitious notions in relation to its virtues are still entertained; and the suspension of the root around the neck by a white riband, has been gravely recommended for the cure of scrofula. The leaves, bruised, and applied in the form of a cataplasm, are used by the vulgar as a remedy in severe headache, and other local pains. The plant, however, is probably inert. An American species, the *V. hastata*, is more bitter than the European, and is said to be emetic. It is not, however, used in regular medical practice. Schoepf states that the root of the *V. urticifolia*, another indigenous species, has been advantageously used in cases of poisoning from the *Rhus Toxicodendron*. It is prepared by boiling it in milk and water along with the inner bark of the white oak.

VERDITER. Two preparations of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. *Blue verditer* is prepared in London from the solution of nitrate of copper, obtained in precipitating silver by copper. According to Gray, this solution is poured hot upon whiting (carbonate of lime), and the mixture stirred every day till the liquor loses its colour, when it is decanted, and fresh portions added till the proper colour

is obtained. By a process for procuring this pigment, invented by Pelletier, the solution of nitrate of copper is decomposed by quicklime, and the precipitate, after being washed, is incorporated intimately with another portion of quicklime. By the former process, a carbonate of copper is obtained, by the latter a mixture of the hydrated oxide of copper and hydrate of lime. *Green verditer* is prepared by precipitating a solution of nitrate of copper by chalk or a white marl, and consists of carbonate of copper mixed with an excess of the calcareous carbonate.

VERONICA OFFICINALIS. *Speedwell.* Several species of Veronica, common to Europe and this country, have been medicinally employed. Of these the *V. officinalis*, and *V. Beccabunga* or *brooklime*, are the most conspicuous. The *V. officinalis* has a bitterish, warm, and somewhat astringent taste; has been considered diaphoretic, diuretic, expectorant, tonic, &c.; and was formerly employed in pectoral and nephritic complaints, hemorrhages, and diseases of the skin, and in the treatment of wounds. The *beccabunga*, which is very succulent, was used in the fresh state with the view of purifying the blood, and as a remedy in scurvy. Both plants, however, are at present out of use.

VISCUM ALBUM. *Mistletoe.* A European evergreen parasitic shrub, growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of druidical superstition. In the religious rites of the druids, the mistletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. The fresh bark and leaves have a peculiar disagreeable odour, and a nauseous, sweetish, slightly bitter taste. The berries, which are white, and of about the size of a pea, abound in a peculiar viscid principle, and are sometimes used in the preparation of birdlime, of which this principle is the basis. At one time the mistletoe was highly esteemed as a remedy in epilepsy, palsy, and other nervous diseases; but it is now out of use. The leaves and wood were given in the dose of a drachm in substance, and of an ounce in decoction. Several species of Viscum grow in the United States, but are not used.

WHITING. This is essentially the same with the prepared carbonate of lime (prepared chalk) of the Pharmacopœias, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which carbonate of lime is requisite. *Paris white* is a variety of the same material.

ZEA MAYS. *Indian Corn.* Common Indian corn contains, according to the late Dr. Gorham, of Boston, 77 per cent. of starch, 3 of a principle analogous to gluten, called *zein*, 2.5 of albumen, 1.45 of sugar, 0.8 of extractive, 1.75 of gum, 1.5 of sulphate and phosphate of lime, 3 of lignin, and 9 of water. The meal, in the form of mush, makes an excellent emollient poultice, much used in hospitals; and a gruel may be prepared from it which is sometimes more grateful to the sick than that made from oat-meal.

ZEDOARY. *Radix Zedoariæ.* There are two kinds of zedoary, the long and the round, distinguished by the official titles of *radix zedoariæ longæ*, and *radix zedoariæ rotundæ*, the former produced by the *Curcuma Zedoaria* of Roxburgh, the latter, as some suppose, by the *Kæmpferia rotunda* of Linn., but according to others, by the *Curcuma Zerumbet* of Roxburgh. Both kinds come from the East Indies. The *long zedoary* is in slices, from an inch and a half to three inches in length, and from half an inch to an inch thick, obtuse at the extremities, and exhibiting the remains of the radical fibres; the *round* is also usually in slices, which are the sections of a roundish root, ending in a point beneath, and divided longitudinally into two parts, each of which is flat on one side, convex on the other, and heart-shaped in its outline. Sometimes the root of the latter variety is entire, and sometimes in quarters instead of halves. It is marked with circular rings on the convex surface, and, like the former, with small projecting points which are the remains of radical fibres. Both are grayish-white on the outside, yellowish-brown within, hard, compact, of an agreeable aromatic odour, and a bitterish, pungent, camphorous taste. The round, however, is less spicy than the long. They yield a volatile oil when distilled with water.

Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debilitated states of the digestive organs. It is not now employed, as it produces no effects which cannot be as well or better obtained from ginger. The dose is from ten grains to half a drachm.

ZERUMBET. *Cassumuniar.* Under these names an East India root was formerly

used, having some analogy in sensible and medical properties to ginger, and ascribed to the *Zingiber Zerumbet* of Roscoe. Some consider the *cassumuniar* as a distinct root, and refer it to the *Zingiber Cassumuniar* of Roxburgh. The difference of opinion is of little importance, as neither of the roots, supposing them not to be the same, is at present to be found in the markets. By some authors the zerumbet has been erroneously confounded with the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish-brown and wrinkled, internally yellowish, hard and tough, of a biting aromatic taste, and a spicy odour.

ZIZYPHUS VULGARIS, Lamarek. *Rhamnus Zizyphus*, Linn. A shrub, or small tree, growing in the countries bordering on the Mediterranean, and cultivated in Italy, Spain, and the South of France. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong pointed stone in the centre. These have the officinal name of *jujubæ*. By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in pectoral complaints. *Jujube paste* consists, properly, of gum Arabic and sugar, dissolved in a decoction of this fruit, and evaporated to the proper consistence. As a demulcent, it is in no respect superior to a paste made with gum Arabic and sugar alone; and the preparation commonly sold in this country under the name, contains in fact none of the fruit.

The fruits of two other species of *Zizyphus*, the *Z. Lotus*, growing in the North of Africa, and the *Z. Jujuba*, a native of the East Indies, possess properties similar to those of the first mentioned species, and are used as food by the inhabitants of the countries where they grow.

NOTE.—Of the articles included in the foregoing list, those upon *Acetic Ether*, *Ammonio-tartrate of Iron*, *Arseniate of Ammonia*, *Arseniate of Iron*, *Bisulphuret of Carbon*, *Bromide of Iron*, *Bromides of Mercury*, *Carburet of Iron*, *Cheltenham Salt*, *Chloride of Potassa*, *Chloride of Silver*, *Chlorine Ethers*, *Citrate of Iron*, *Crabs' Claws*, *Crab Stones*, *Cyanuret of Zinc*, *Diaphoretic Antimony*, *Dippel's Animal Oil*, *Ferrocyanuret of Zinc*, *Glass of Antimony*, *Gold*, *Hydriodic Acid*, *Hydrocyanic Ether*, *Indelible Ink*, *Iodide of Ammonium*, *Iodide of Arsenic*, *Iodide of Barium*, *Iodide of Silver*, *Iodide of Starch*, *Iodide of Zinc*, *Iodo-hydrargyrate of Potassium*, *Lactate of Iron*, *Lactic Acid*, *Muriatic Ether*, *Artificial Musk*, *Nitrate of Soda*, *Nitrosulphate of Ammonia*, *Oxalic Acid*, *Oxide of Silver*, *Platinum*, *Sesquinitrate of Iron*, *Solution of Hydriodate of Arsenic and Mercury*, *Soot*, *Sulphate of Alumina*, *Sulphocyanuret of Potassium*, *Tannate of Lead*, and *Tutty* were written by Dr. Bache; the remainder by Dr. Wood.

II. ART OF PRESCRIBING MEDICINES.

THE physician should be acquainted not only with the properties of medicines, and the diseases to which they are respectively applicable, but also with the art of prescribing them, so that they may be adapted to the peculiarities of individual patients, and, by the mode in which they are administered, may produce the greatest curative effect with the least possible inconvenience. In relation to these points, a few general rules will be useful for the guidance of the young practitioner, although much must be left to his own judgment and discretion. We shall compress the remarks which we have to offer, under the two heads of the quantity or dose in which medicines may be given, and the mode of their exhibition.

1. DOSE OF MEDICINES.—In the body of the work, the quantity has been stated in which each medicine must ordinarily be given to produce its peculiar effects in the adult patient. But there are various circumstances which modify the dose, and demand attention on the part of the practitioner.

The age of the patient is the most important of these circumstances. The young require a smaller dose than those at maturity, to produce an equal effect; and the old, though their systems are, perhaps, less susceptible to the action of medicines than those of the middle-aged, cannot bear an equally forcible impression. The following table of Gaubius, exhibiting the doses proportioned to the age, is frequently referred to.

The dose for a person of middle age being	1 or 1 drachm,
That of a person from 14 to 21 years will be	$\frac{2}{3}$ or 2 scruples,
7 to 14 “ “	$\frac{1}{2}$ or $\frac{1}{2}$ a drachm,
4 to 7 “ “	$\frac{1}{3}$ or 1 scruple,
of 4 years “ “	$\frac{1}{4}$ or 15 grains,
3 “ “ “	$\frac{1}{6}$ or 10 grains,
2 “ “ “	$\frac{1}{8}$ or 8 grains,
1 “ “ “	$\frac{1}{12}$ or 5 grains.

We prefer the following simple scheme of Dr. Young, which we extract from Paris's Pharmacologia.

“For children under twelve years, the doses of most medicines must be diminished in the proportion of the age to the age increased by 12; thus at two years to $\frac{1}{7}$ —viz, $\frac{2}{2+12} = \frac{1}{7}$. At twenty-one the full dose may be given.”

To the above rule some exceptions are offered in particular medicines, which require to be given to children in much larger proportional doses than those above stated. Such are castor oil and calomel, a certain quantity of which will in general not produce a greater effect in a child two or three years old than double the quantity in an adult.

Sex, temperament, and idiosyncrasy have also an influence upon the dose, and should be kept in view in prescribing. Females usually require somewhat smaller doses than males, and those of sanguine temperament than the phlegmatic. Constitutional peculiarities, called idiosyncrasies, often exist in individuals, rendering them more than usually susceptible or insusceptible to the action of certain remedies, the dose of which must be modified accordingly. Thus in some persons a grain or two of calomel will excite

salivation, while in others scarcely any quantity which can be safely administered will produce this effect. Sometimes, moreover, a medicine operates on an individual in a manner wholly different from its ordinary mode. In all such cases experience is the only sure guide; but the occasional existence of these peculiarities indicates the propriety of making particular inquiries in relation to the idiosyncrasies of those patients, for whom we may be called for the first time to prescribe.

Habit is another important circumstance which modifies the dose of medicines. Generally speaking, the susceptibility to the action of medicines is diminished by their frequent and continued use; and in order to maintain a given impression, the quantity must be regularly increased. This is especially true in regard to the narcotics, which are sometimes borne in enormous doses by those habituated to their use. It is a good practical rule in prescribing, when circumstances demand the continuance, for a considerable length of time, of some particular effect, to vary the medicine, and employ successively several of the same general powers, so as not too rapidly to exhaust the susceptibility to the action of any individual remedy. Another important practical rule connected with the influence of habit is, when any medicine, which from its nature is of variable strength, has been employed for some time in increasing doses, to reduce the dose upon resorting to a new parcel, until its relative strength has been ascertained. A neglect of this precaution, in cases where the last parcel happened to be more powerful than that previously employed, has sometimes been followed by very serious consequences.

2. MODE OF ADMINISTERING MEDICINES.—This has reference both to the combination of medicines with one another, and the form in which they are exhibited.

Simplicity in prescription is always desirable when no object is to be gained by deviating from it. Remedies should never be mixed together without a definite purpose, nor with the vague hope that out of the number prescribed some one may perchance produce a salutary impression. Those exceedingly complex prescriptions, formerly so much in vogue, of which the ingredients were so numerous as to render altogether impossible a reasonable estimate of their bearing on each other, or their effects on disease, have been generally abandoned by modern practitioners. The only ground upon which any of them can be justifiably retained is that, by very frequent trials, through a long course of years, and in various states of disease, their influence on the system may have been fully ascertained, so that they may be considered rather in the light of a single remedy than a compound of many. Upon this ground, however, no prudent physician would attempt to originate such combinations. In mixing medicines, he would proceed no further than he would be justified in doing by a clear knowledge of the properties and mutual relations of the several ingredients, and their fitness to answer some particular indication in the treatment of disease. There are certain principles upon which medicines may be advantageously combined, and which it may not be amiss to mention for the benefit of the young practitioner.

Remedies of the same general character may be given in connexion, in order to increase their energy, or to render their action more certain. It has been well ascertained that substances thus combined will often act vigorously, when severally they would produce comparatively little effect; and it sometimes happens that, while their activity is augmented, they are at the same time rendered less irritating, as in the case of the drastic cathartics. (See *Pilulæ Catharticæ Compositæ*.)

Different medicines are very often mixed together, in order to meet different and coexisting indications, without any reference to the influence which they may reciprocally exert on each other. Thus in the same patient we not unfrequently meet with debility of stomach and constipation of the bowels, connected with derangement of the hepatic function. To answer the indications presented by these morbid conditions, we may properly combine in the same dose, a tonic, cathartic, and mercurial alterative. For similar reasons we often unite tonics, purgatives, and emmenagogues, anodynes and diaphoretics, emetics and cathartics, antacids, astringents, and tonics; and scarcely two medicines can be mentioned, not absolutely incompatible with each other, which may not occasionally be combined with advantage to counteract coexisting morbid actions.

Another very important object of combination, is the modification which is thereby effected in the actions of medicines differing from each other in properties. In this way new powers are sometimes developed, and those previously existing are greatly increased. Examples of such a result are afforded in the officinal powder of ipecacuanha and opium, and in the combination of squill and calomel; the former operating as a diaphoretic, the latter as a diuretic, beyond the capabilities of either of their constituents. The effects of one medicine are, in numerous instances, increased by the influence of another in augmenting the natural susceptibility of the system to its action. Thus bitters enable cathartics to operate in smaller doses; purgatives awaken the dormant susceptibility to the action of mercury; and stimulants excite the torpid stomach, so that it will receive impressions from various medicines before inoperative. In some instances, the action of one medicine is promoted by that of another apparently of a nature wholly opposite. Thus, when calomel and opium are given in colic, the purgative operation of the former is facilitated by the relaxation of intestinal spasm produced by the latter. Medicines, in addition to the effects for which they are administered, very frequently produce disagreeable symptoms, which may be moderated or altogether prevented by combination with other medicines; and this object may usually be accomplished, without in the least degree interfering with the remediate influence desired. Thus the griping produced by cathartics, and the nausea by these and various other medicines, may often be corrected by the simultaneous use of aromatics. To cover the disagreeable taste or odour of certain medicines, and to afford a convenient vehicle for their administration, are also important objects of combination; as upon these circumstances often depend the acceptability of the medicine to the stomach, and even the possibility of inducing the patient to swallow it. Substances should be preferred as vehicles which are calculated to render the medicine acceptable to the palate and stomach, and in other ways to correct its disagreeable effects; as syrups for powders, the aromatic waters for medicines given in the form of mixture, and carbonic acid water for the neutral salts.

But in the mixing of medicines, care should be taken that they are neither chemically nor physiologically incompatible; in other words, that they are not such as will react on each other so as to produce new and unexpected combinations, nor such as will exert contrary and opposite effects upon the system. Thus when the operation of an acid is desired, an alkali should not be given at the same time, as they unite to form a third substance entirely different from either; nor should a soluble salt of lime, baryta, or lead, be given with sulphuric acid or a soluble sulphate, as decomposition would ensue, with the production of an inert compound. So also, in relation to physiological incompatibility, diaphoretics and diuretics should not, as a

general rule, be united with a view to their respective effects; as these are to a certain extent incompatible, one being diminished by whatever has a tendency to increase the other. There are cases, however, in which we may advantageously combine medicines with a view to their chemical reaction, as in the instance of the effervescing draught; and circumstances sometimes call for the union of remedies apparently opposite, as in the case of colic before alluded to, in which opium may be advantageously combined with purgatives. Still, such combinations should never be formed, unless with a full understanding of their effects, and a special reference to them.

The *form in which medicines are exhibited*, is often an object of considerable importance. By variation, in this respect, according to the nature of the medicine, the taste of the patient, or the condition of the stomach, we are frequently enabled to secure the favourable operation of remedies, which without such attention might prove useless or injurious. Medicines may be given in the solid state, as in the form of powder, pill, troche, or electuary; in the state of mixture, in which a solid is suspended in a liquid, or one liquid is mechanically mixed with another in which it is insoluble; or in the state of solution, under which may be included the various forms of infusion, decoction, tincture, wine, vinegar, syrup, honey, and oxymel. Of these different forms we have already treated sufficiently at large, under their respective heads, in the second part of this work.

In writing extemporaneous prescriptions, neatness, order, and precision, should always be observed; as, independently of the pleasing moral effect inseparable from these principles in all things, a positive practical advantage results, in the greater accuracy which the habit of attending to them gives to the prescriber, and the comparative certainty which they afford that his directions will be strictly complied with. As a general rule, when medicines are combined in prescription, that should come first in order which is considered as the most prominent and important, next the adjuvant or corrigent, and lastly the vehicle. Sometimes, however, it is important to indicate to the apothecary the succession in which the substances should be combined in reference to the perfection of the mixture, and this may render convenient a deviation from the order above mentioned. The physician should always be careful either to write out the full name of the medicine, or to employ such abbreviations as are not likely, by the misunderstanding of an ill-formed letter, to lead into error. Very serious and even fatal mistakes have been occasioned by a neglect of this precaution. The formulæ of the several Pharmacopœias which are detailed in this work, will serve as good examples for the guidance of the young practitioner. The following table explains the signs and abbreviations habitually used in prescription. The formulæ afterwards given will serve to illustrate the ordinary mode of prescribing, while they exhibit combinations of medicines frequently employed in practice.

W.

Table of Signs and Abbreviations.

R	Recipe.	Take.	Collyr.	Collyrium.	An eye-water.
aa	Ana.	Of each.	Cong.	Congius vel Congii.	A gallon or gallons.
lb	Libra vel libræ.	A pound or pounds.	Decoet.	Decoctum.	A decoction.
℥	Uncia vel uncia.	An ounce or ounces.	Ft.	Fiat.	Make.
ʒ	Drachma vel drachmæ.	A drachm or drachms.	Garg.	Gargarysma.	A gargle.
ʒ	Scrupulus vel scrupuli.	A scruple or scruples.	Gr.	Granum vel grana.	A grain or grains.
o	Octarius vel octarii.	A pint or pints.	Gtt.	Gutta vel guttæ.	A drop or drops.
f℥	Fluiduncia vel fluiduncia.	A fluidounce or fluidounces.	Haust.	Haustus.	A draught.
f℥	Fluidrachma vel fluidrachmæ.	A fluidrachm or fluidrachms.	Infus.	Infusum.	An infusion.
℥	Minimum vel minima.	A minim or minims.	M.	Misce.	Mix.
Chart.	Chartula vel Chartulæ.	A small paper or papers.	Mass.	Massa.	A mass.
Coch.	Cochlear vel cochlearia.	A spoonful or spoonfuls.	Mist.	Mistura.	A mixture.
			Pil.	Pilula vel pilulæ.	A pill or pills.
			Pulv.	Pulvis vel pulve- res.	A powder or powders.
			Q. S.	Quantum suffi- cit.	A sufficient quantity.
			S.	Signa.	Write.
			Ss.	Semis.	A half.

Examples of Common Extemporaneous Prescriptions.

POWDERS.

- R** Antimonii et Potassæ Tartratis gr. i.
Pulveris Ipecacuanhæ ʒi.
Fiat pulvis.
S. To be taken in a wineglassful of sweetened water.
An active emetic.
- R** Hydrargyri Chloridi Mitis,
Pulveris Jalapæ, aa gr. x.
Misce.
S. To be taken in syrup or molasses.
An excellent cathartic in the commence-
ment of bilious fevers, and in hepatic con-
gestion.
- R** Pulveris Jalapæ gr. x.
Potassæ Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A hydragogue cathartic used in dropsy
and scrofulous inflammation of the joints.
- R** Sulphuris ʒi.
Potassæ Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A laxative, used in piles and cutaneous
diseases.
- R** Pulveris Rhei gr. x.
Magnesiæ ʒss.
Fiat pulvis.
- S. To be taken in syrup or molasses.
A laxative and antacid, used in diarrhœa,
dyspepsia, &c.
- R** Pulveris Scillæ gr. xii.
Potassæ Nitratis ʒi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken twice or three times
a day in syrup or molasses.
A diuretic employed in dropsy.
- R** Potassæ Nitratis ʒi.
Antimonii et Potassæ Tartratis gr. i.
Hydrarg. Chlorid. Mitis gr. vi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every two hours in
syrup or molasses.
A refrigerant, diaphoretic, and altera-
tive, used in bilious fevers; usually called
nitrous powders.
- R** Pulveris Guaiaci Resinæ,
Potassæ Nitratis, aa ʒi.
Pulveris Ipecacuanhæ gr. iii.
Opii gr. ii.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every three hours in
syrup or molasses.
A stimulant diaphoretic, used in rheu-
matism and gout after sufficient depletion.

R Ferri Subcarbonatis,
 Pulveris Colombæ,
 Pulveris Zingiberis, āā ʒi.
 Fiat pulvis, in chartulas sex dividendus.

S. One to be taken three times a day in syrup or molasses.

A tonic, used in dyspepsia and general debility.

PILLS.

R Pulveris Aloës,
 Pulveris Rhei, āā ʒss.
 Saponis ʒi.
 Misce, et cum aquâ fiat massa in pilulas viginti dividenda.

S. Two or three to be taken daily, at bed-time, or before a meal.

An excellent laxative in habitual constipation.

R Massæ Pilularum Hydrargyri,
 Pulveris Aloës,
 Pulveris Rhei, āā ʒi.
 Misce, et cum aquâ fiat massa in pilulas viginti dividenda.

S. Three to be taken at bed-time.

An alterative and laxative, useful in constipation with deranged or deficient hepatic secretion.

R Pulveris Aloës,
 Extracti Quassie, āā ʒi.
 Olei Anisi ℥x.
 Syrupi, q. s.
 Misce, et fiat massa in pilulas triginta dividenda.

S. Two to be taken once, twice, or three times a day.

A laxative, tonic, and carminative, useful in dyspepsia.

R Pulveris Scillæ ʒi.
 Hydrargyri Chloridi Mitis gr. x.
 Pulveris Acaciæ,
 Syrupi, āā q. s.
 Misce, et fiat massa in pilulas decem dividenda.

S. One to be taken two or three times a day.

A diuretic and alterative, much used in dropsy, especially when complicated with organic visceral disease.

R Pulveris Opii gr. iv.
 Pulveris Ipecacuanhæ gr. xviii.
 Pulveris Acaciæ,
 Syrupi, āā q. s.
 Misce, et fiat massa in pilulas duodecim dividenda.

S. One to be taken after each stool.

An anodyne diaphoretic, useful in dysentery and diarrhœa after the use of laxatives.

R Pulveris Opii,
 Pulveris Ipecacuanhæ, āā gr. iii.
 Hydrargyri Chloridi Mitis gr. vi.
 Pulveris Acaciæ,
 Syrupi, āā q. s.
 Misce, et fiat massa in pilulas tres dividenda.

S. One or more to be taken at bed-time, or according to circumstances.

An anodyne, diaphoretic, and alterative, very useful in diarrhœa, dysentery, typhoid pneumonia, and various other diseases.

R Plumbi Acetatis in pulverem triti gr. xii.
 Pulveris Opii gr. i.
 Pulv. Acaciæ,
 Syrupi, āā q. s. ut fiat massa in pilulas sex dividenda.

S. One every two, three, or four hours.

An astringent much employed in hæmoptysis and uterine hemorrhage.

MIXTURES.

R Magnesie ʒi.
 Syrupi f ʒi.
 Tere simul, et affunde
 Aquæ Acidi Carbonici f ʒiv.
 Fiat haustus.

S. To be taken at a draught, the mixture being well shaken.

An agreeable mode of administering magnesia.

R Mannæ ʒi.
 Fœniculi contusi ʒi.
 Aquæ bullientis f ʒiv.
 Fiat infusum et cola; dein adjice
 Magnesie Carbonatis ʒii.
 Ft. mist.

S. One third to be taken every three or four hours till it operates, the mixture being shaken.

An excellent carminative and mild laxative in flatulence and pain in the bowels.

R Olei Ricini f ʒi.
 Pulveris Acaciæ,
 Sacchari, āā ʒii.
 Aquæ Menthæ Piperitæ f ʒiii.
 Acaciam et saccharum cum fluidunciâ dimidiâ aquæ menthæ tere; dein oleum adjice, et contere; denique aquam reliquam paulatim infunde, et omnia misce.

S. To be taken at a draught, the mixture being well shaken.

R Olei Ricini f̄zi.

Vitellum ovi unius.

Tere simul, et adde

Syrupi f̄zss.

Aquæ Menthæ Piperitæ f̄zii.

Ft. haustl.

S. To be taken at a draught, the mixture being well shaken.

This and the preceding formula afford convenient modes of administering castor oil, when the stomach is irritable. Any other fixed oil may be given in the same way.

R Olei Ricini f̄ziss.

Tincturæ Opii ℥xxx.

Pulv. Acaciæ,

Sacchari, āā zii.

Aquæ Menthæ Viridis f̄ziv.

Acaciam et saccharum cum paululo aquæ menthæ tere; dein oleum adjice, et iterum tere; denique aquam reliquam paulatim infunde, et omnia misce.

S. A tablespoonful to be taken every hour or two hours till it operates, the mixture being each time well shaken.

Used as a gentle laxative in dysentery and diarrhœa. It is usually known by the name of *oleaginous mixture*.

R Elaterii gr. i.

Spiritus Ætheris Nitrici f̄zii.

Tincturæ Scillæ,

Oxymellis Colchici, āā f̄zss.

Syrupi, f̄zi.

Ft. mist.

S. A teaspoonful to be taken three or four times a day in a little water.

Diuretic, used by Ferriar in dropsy.

R Copaibæ,

Spiritus Lavandulæ Comp. āā f̄zii.

Mucilaginis Acaciæ f̄zss.

Syrupi f̄ziii.

Simul tere; dein paulatim affunde

Aquæ f̄ziv.

Misce.

S. A tablespoonful to be taken four times a day or more frequently.

Given in chronic catarrhs, and chronic nephritic affections. The dose must be larger in gonorrhœa.

*Neutral Mixture.***R Acidi Citrici zii.**

Olei Limonis ℥i.

Simul tere et adde

Aquæ f̄ziv.

Liqua, et adde

Potassæ Carbonatis q. s. ad saturand.

Misce et per linteum cola.

Or

R Succo Limonis recentis f̄ziv.

Potassæ Carbonatis q. s. ad saturandum.

Misce et cola.

S. A tablespoonful to be given with an equal quantity of water every hour or two hours.

An excellent diaphoretic in fever.

*Effervescing Draught.***R Potassæ Carbonatis zii.**

Aquæ f̄ziv.

Liqua.

Or

R Potassæ Bicarbonatis ziii.

Aquæ f̄ziv.

Liqua.

S. Add a tablespoonful of the solution to the same quantity of lemon or lime-juice, previously mixed with a tablespoonful of water; and give the mixture, in the state of effervescence, every hour or two hours.

An excellent diaphoretic and anti-emetic in fever with nausea or vomiting.

*Brown Mixture.***R Pulv. Extract. Glycyrrhizæ,**

Pulv. Acaciæ, āā zii.

Aquæ ferventis f̄ziv.

Liqua, et adde

Vini Antimonii f̄zii.

Tincturæ Opii ℥xx.

Ft. Mist.

S. A tablespoonful to be taken occasionally.

Expectorant, demulcent, and anodyne, useful in catarrhal affections.

R Antimonii et Potassæ Tartratis gr. i.

Syrupi Scillæ,

Liquoris Morphiz Sulphatis, āā f̄zss.

Pulveris Acaciæ zii.

Syrupi f̄zss.

Aquæ fluvialis f̄ziv.

Ft. Mist.

S. A tablespoonful to be taken occasionally.

An expectorant and anodyne cough mixture.

R Acidi Nitrosi f̄zi.

Tincturæ Opii gtt. xl.

Aquæ Camphoræ f̄zviii.

Misce.

S. One-fourth to be taken every three or four hours.

Hope's mixture, used in dysentery, diarrhœa, and cholera.

R Camphoræ zi.

Myrrhæ zss.

Pulv. Acaciæ,

Sacchari, āā zii.

Aquæ f̄zvi.

Camphoram cum alcoholis paululo in pulverem tere; dein cum myrrhâ, acaciâ, et saccharo contere; denique cum aquâ paulatim instillatâ misce.

S. A tablespoonful to be taken for a dose, the mixture being well shaken.

A convenient form for administering camphor.

R Cretæ Præparatæ ðiv.
Massæ Pil. Hydrarg. gr. viii.
Tincturæ Opii gtt. viii.
Pulveris Acaciæ,
Sacchari, āā ʒi.
Aquæ Cinnamomi,
Aquæ, āā fʒi.

Solida simul tere, dein liquida paulatim inter terendum adjice, et omnia misce.

S. A teaspoonful to be taken for a dose, the mixture being well shaken.

An antacid and alterative mixture, well adapted to infantile diarrhœa with white

stools. The dose mentioned is for a child a year or two old, and may be repeated four or six times in twenty-four hours.

R Pulveris Kino ʒii.
Aquæ bullientis fʒvi.
Fiat infusum et cola; dein secundum artem admisce
Cretæ Præparatæ ʒiii.
Tincturæ Opii fʒss.
Spirittus Lavandulæ Compositi fʒss.
Pulveris Acaciæ,
Sacchari, āā ʒii.

S. A tablespoonful to be taken for a dose, the mixture being well shaken.

Astringent and antacid, useful in diarrhœa.

SOLUTIONS.

R Magnesiæ Sulphatis ʒi.
Syrupi Limonis fʒi.
Aquæ Acidi Carbonici fʒvi.
Misce.
S. To be taken at a draught.
An agreeable mode of administering sulphate of magnesia.

R Potassæ Nitratis ʒi.
Antimonii et Potassæ Tartratis gr. i.
Aquæ fluvialis fʒiv.
Liqua.
S. A tablespoonful to be taken every two hours.
A refrigerant diaphoretic used in fevers.

R Magnesiæ Sulphatis ʒi.
Antimonii et Potassæ Tartratis gr. i.
Succi Limonis recentis fʒi.
Aquæ fʒiii.
Misce.
S. A tablespoonful to be taken every two hours till it operates upon the bowels.
Useful in fevers.

R Quiniæ Sulphatis gr. xii.
Acidi Sulphurici Aromatici ℥xx.
Syrupi fʒss.
Aquæ Menthæ Piperitæ fʒi.
Misce.
S. A teaspoonful to be taken every hour or two hours.
A good mode of administering sulphate of quinia in solution.

INFUSIONS.

R Sennæ ʒiii.
Magnesiæ Sulphatis,
Mannæ, āā ʒss.
Fœniculi ʒi.
Aquæ bullientis Oss.
Maceræ per horam in vase leviter clauso et cola.
S. Give a teacupful every three or four hours till it operates.
An excellent purgative in febrile complaints.

R Colombæ contusæ,
Zingiberis contusi, āā ʒss.
Sennæ ʒii.
Aquæ bullientis Oi.
Maceræ per horam in vase leviter clauso et cola.
S. A wineglassful to be taken morning, noon, and evening, or less frequently if it operate too much.
An excellent remedy in dyspepsia with constipation and flatulence.

R Spigeliæ ʒss.
Sennæ ʒii.
Mannæ ʒi.
Fœniculi ʒii.
Aquæ bullientis Oi.
Maceræ per horam in vase leviter clauso et cola.
S. A wineglassful to be given to a child from two to four years old, three or four times a day.
A powerful anthelmintic.

R Pulveris Cinchonæ Rubræ ʒi.
Acidi Sulphurici Aromatici fʒi.
Aquæ Oi.
Maceræ per horas duodecim, subinde agitans.
S. A wineglassful of the clear liquid to be taken for a dose.
A good method of administering Peruvian bark in cold infusion.

III. TABLES OF WEIGHTS AND MEASURES.

APOTHECARIES' WEIGHT. *U. S., Lond., Ed., Dub.*

Pound.	Ounces.	Drachms.	Scruples.	Grains.
℔ 1 =	12 =	96 =	288 =	5760
	℥ 1 =	8 =	24 =	480
		ʒ 1 =	3 =	60
			ʒ 1 =	gr. 20

The Imperial Standard Troy weight at present recognised by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains, but differs from it in the division of the ounce, which, according to the former scale, contains twenty pennyweights, each weighing twenty-four grains.

AVOIRDUPOIS WEIGHT.

1 fluidounce	= 1.04158725 ounces.

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures, the calculator may proceed as if the liquid was water, and the obtained measure will be to the true measure *inversely* as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight *directly* as the specific gravity.

FRENCH DECIMAL WEIGHTS AND MEASURES.

The French *metrical* system is based upon the idea of employing, as the unity of all measures, whether of length, capacity, or weight, a uniform unchangeable standard, adopted from nature, the multiples and subdivisions of which should follow in decimal progression. To obtain such a standard, the length of one-fourth part of the terrestrial meridian, extending from the equator to the pole, was ascertained. The ten millionth part of this arc was chosen as the unity of measures of length, and was denominated *metre*. The cube of the tenth part of the metre was taken as the unity of measures of capacity, and denominated *litre*. The weight of distilled water, at its greatest density, which this cube is capable of containing, was called *kilogramme*, of which the thousandth part was adopted as the unity of weight, under the name of *gramme*. The multiples of these measures, proceeding in the decimal progression, are distinguished by employing the prefixes, *deca*, *hecto*, *kilo*, and *myria*, taken from the Greek numerals; and the subdivisions, following the same order, by *deci*, *centi*, *mili*, from the Latin numerals.

The <i>metre</i> , or unity of length, at 32°	= 39·371	English inches at 62°.
The <i>litre</i> , or unity of capacity,	= 61·028	English cubic inches.
The <i>gramme</i> , or unity of weight,	= 15·434	Troy grains.

Upon this basis the following tables, which we take with some slight alterations from the Edinburgh New Dispensatory, have been constructed. It was ascertained by accurate examination at the London Mint, that the *gramme* is only 15·434 Troy grains, though sometimes stated at 15·444 grains.

MEASURES OF LENGTH.

The metre being at 32°, and the foot at 62°.

Though the decimal system of weights and measures was established by law in France, it was found impossible to procure its general adoption by the people, who obstinately adhered to the old *poids de marc* and its divisions; or, if they adopted the new weights, gave them the names of the old weights to which they most nearly approached. Thus the *kilogramme*, which is equal to 18,827 $\frac{15}{100}$ French grains, or 2 pounds 5 gros 35 $\frac{15}{100}$ grains *poids de marc*, was divided into two parts, and the half of it called a pound. One reason for this adherence to the old weights was the convenience of division into halves, quarters, &c., of which the new were not susceptible. To obviate this difficulty the imperial government legalized the employment of the half kilogramme as the unity of weight, under the name of pound, and allowed this to be divided into half pounds, quarters, eighths, ounces, &c., as in the old *poids de marc*. The new pound is distinguished by the name of *metrical pound*, and has been adopted to a considerable extent; while the old weights are retained by some, particularly by the apothecaries and gold-

smiths; so that three systems are now more or less in use in France—the original *poids de marc*, the decimal system, and the metrical pound with its divisions. The following table represents the relative value of these different weights.

Decimal System.		Poids de Marc.				Metrical Pound.			
		lb	oz.	dr.	gr.	lb	oz.	dr.	gr.
1 centigramme	=	0	0	0	0.19	=	0	0	0.18
1 decigramme	=	0	0	0	1.88	=	0	0	1.84
1 gramme	=	0	0	0	18.83	=	0	0	18.43
1 decagramme	=	0	0	2	44.27	=	0	0	40.32
1 hectogramme	=	0	3	2	10.71	=	0	3	1 43.2
1 kilogramme	=	2	0	5	35.15	=	2	0	0

Poids de Marc.		Grammes.		Metrical Pound.		Grammes.	
1 grain	=	0.0531		1 grain	=	0.054	
24 grains or \mathfrak{z} i	=	1.2747		24 grains or \mathfrak{z} i	=	1.302	
72 grains or \mathfrak{z} ii	=	3.8242		72 grains or \mathfrak{z} ii	=	3.906	
1 ounce	=	30.5941		1 ounce	=	31.25	
1 pound	=	489.5058		1 pound	=	500	

The following table is taken from Christison's Dispensatory, and was calculated chiefly from data furnished in Soubeiran's *Traité de Pharmacie*.

Table of certain foreign Apothecaries' Weights, exhibiting the value of their different denominations in Troy Grains.

		Pound.	Ounce.	Drachm.	Scruple.	Grain.
French (old)	-	5670.5	472.50	59.10	19.70	0.820
Spanish	-	5320.4	443.49	55.44	18.47	0.769
Tuscan	-	5240.3	436.67	54.58	18.19	0.758
Roman	-	5235.0	436.25	54.53	18.17	0.757
Austrian	-	6495.1	541.25	67.65	22.55	1.127
German or Nuremburg	}	5524.8	460.40	57.55	19.18	0.960
Russian						
Prussian	-	5415.1	451.26	56.40	18.80	0.940
Dutch	}	5695.8	474.64	59.33	19.78	0.988
Belgian						
Swedish	-	5500.2	458.34	57.29	19.09	0.954
Piedmontese	-	4744.7	395.39	49.45	16.48	0.824
Venetian	-	4661.4	388.45	48.55	16.18	0.809

Of these weights, all, except the French, Spanish, Tuscan, and Roman, (first named in the table,) are divided into parts corresponding with those of the English Apothecaries' weight. In these four, the drachm contains 72 instead of 60 grains, and the scruple 24 instead of 20 grains; but, as in the English, there are 3 scruples in the drachm, 8 drachms in the ounce, and 12 ounces in the pound.

APPROXIMATE MEASUREMENT.

For the sake of convenience, in the absence of proper instruments, we often make use of means of measurement, which, though not precise nor uniform, afford results sufficiently accurate for ordinary purposes. Of this kind are certain household implements, of a capacity approaching to uni-

formity, and corresponding to a certain extent with the regular standard measures. Custom has attached a fixed value to these implements, with which it is proper that the practitioner should be familiar; although their capacity, as they are now made, generally somewhat exceeds that at which they were originally and still continue to be estimated.

A *tea-cup* is estimated to contain about four fluidounces, or a gill.

A *wineglass* - - - - - two fluidounces.

A *tablespoon* (cochlear magnum) - half a fluidounce.

A *teaspoon* (cochlear parvum) - a fluidrachm.

Small quantities of liquid medicines are often estimated by *drops*, each of which is usually considered equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of watery fluids is, on an average, about this size; but the same is by no means the case with all medicinal liquids, and the drop even of the same fluid varies exceedingly in bulk, according to the circumstances under which it is formed. This is, therefore, a very uncertain mode of estimating the quantity of liquids, and should be entirely superseded in the shops, where minim measures may be had.

The results stated in the following table were obtained by Mr. E. Durand, of Philadelphia. (See *Journ. of the Philadelphia College of Pharmacy*, i. 169.) They may be relied on as accurate; but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned; for, under other circumstances than those of Mr. Durand's experiments, entirely different results might be obtained as relates to each liquid. The preparations experimented with were those of the first edition of the U. S. Pharmacopœia.

Table, exhibiting the number of Drops of different Liquids, equivalent to a Fluidrachm.

	Drops.		Drops.

liquid, sp. gr. 1.5 - - - - -	1 acid+1½ water	67.65
nitrous - - - - -	$N+4O$	46.15

* This table includes the equivalents of all the simple bodies, although several of them are not used in medicine. It also embraces a few compounds which are not used in pharmacy, but which are inserted on account of their general importance.

† By modern chemists, the simple bodies are designated by letters called *symbols*. The initial letter of the name is the symbol, whenever it is distinctive; but when several simple bodies have names beginning with the same letter, the plan adopted is to represent one of them by the initial letter, and the rest by the initial letter, with some other associated with it. Thus C stands for carbon, Cd for cadmium, Ca for calcium, Ce for cerium, Cl for chlorine, Cr for chromium, Co for cobalt, Cu for copper, &c. The use of these symbols saves time and space in designating the composition of compounds. Where a single equivalent is intended to be designated, the symbol of the body is simply given; but where several equivalents are to be represented, the symbol is preceded by a figure, indicating the number. Thus C means one equivalent of carbon; 2C, two equivalents, and so on. The group of letters and figures, thus used to denote the composition of any body, is called the *formula* of such body. In all cases, the constitution of compounds, however complex, may be expressed by *formulæ*; but in the above table this mode of notation is adopted only for the less complex compounds. These symbols are those employed by Berzelius, and should not be varied from, for fear of destroying their usefulness by creating confusion.

V. CORRESPONDENCE BETWEEN DIFFERENT THERMOMETERS.

In *Fahrenheit's* thermometer, which is universally employed in this country and Great Britain, the freezing point of water is placed at 32° , and the boiling point at 212° , and the number of intervening degrees is 180.

The *Centigrade* thermometer, which has long been used in Sweden, under the name of Celsius's thermometer, and is now most generally employed on the continent of Europe, marks the freezing point *zero*, and the boiling point 100° .

In *Reaumur's* thermometer, used in France before the revolution, the freezing point is at zero, and the boiling point at 80° .

In *De Lisle's* thermometer, used in Russia, the graduation begins at the boiling point, which is marked *zero*, while the freezing point is placed at 150° .

From the above statement it is evident that 180 degrees of Fahrenheit are equal to 100° of the centigrade, 80° of Reaumur, and 150° of De Lisle; or 1 degree of the first is equal to $\frac{5}{9}$ of a degree of the second, $\frac{4}{9}$ of a degree of the third, and $\frac{5}{6}$ of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero of Fahrenheit is 32° below the point at which that of the centigrade and of Reaumur is placed, this number must be taken into account in the calculation. The following propositions will embrace all the cases which can arise in relation to the three last mentioned thermometers. That of De Lisle is seldom or never referred to in works which are read in this country.

1. If any degree on the *centigrade* scale, either above or below zero, be multiplied by 9 and divided by 5, or if any degree of *Reaumur* above or below zero be multiplied by 9 and divided by 4, the quotient will, in either case, be the number of degrees above or below 32° or the freezing point of *Fahrenheit*.

2. The number of degrees between any point of *Fahrenheit's* scale and 32° , if multiplied by 5 and divided by 9, will give the corresponding point on the *centigrade*; if multiplied by 4 and divided by 9, will give the corresponding point on the scale of *Reaumur*.

3. Any degree of the *centigrade* multiplied by 4 and divided by 5, will give the corresponding degree of *Reaumur*; and conversely, any degree of *Reaumur* multiplied by 5 and divided by 4, will give the corresponding degree of the *centigrade*.

VI. TABLES,

SHOWING THE SPECIFIC GRAVITY CORRESPONDING WITH THE SEVERAL DEGREES OF DIFFERENT HYDROMETERS IN USE.

Baumé's hydrometer is usually employed in France. In this instrument, the sp. gr. of distilled water is assumed as the zero of the descending scale, in relation to fluids heavier than itself, while it is assumed as 10 on the ascending scale, in relation to lighter fluids. In the Pharmacopœia Batava, a modification of the instrument has been adopted, in which the sp. gr. of distilled water has been assumed as the zero of both scales. Beck's hydrometer is used in Germany. In the following tables, the specific gravity of liquids is given corresponding with the several degrees of these three hydrometers.

For Liquids lighter than Water.

The French Codex employs Baumé's hydrometer to indicate the density of liquids heavier than water; but, for those lighter than water, it has recourse to the instrument of *Cartier*, as the one most diffused in commerce. This differs from Baumé's only in a slight modification of the scale. In both, the lowest point is 10°; but 30° of Cartier corresponds with 32° of Baumé, so that 20 degrees of the former are equivalent to 22 of the latter. The following table, extracted from the Codex, shows the value of the several degrees of Baumé's scale in those of Cartier's. The *centesimal alcoholmeter* of Gay-Lussac is applicable only to alcohol. The scale of this instrument is divided into 100 unequal degrees, the zero corresponding to pure water, and 100° to absolute alcohol; and every intermediate degree expresses the per centage of pure alcohol contained in the liquors examined. Thus, when the instrument stands at 40°, in any alcoholic liquid, it indicates that 100 parts of the liquid contain 40 of pure alcohol and 60 of water. But as it was graduated for the temperature of 59° of Fahrenheit, the liquors to be tested should be brought to that temperature. In page 62 of this Dispensatory is a table indicating the specific gravity corresponding with each per centage of alcohol, and consequently with each degree of the alcoholmeter; and as, in the second table given below, the value of Cartier's degrees in those of the alcoholmeter is stated, there can be no difficulty in converting the degrees of any one of these instruments into those of another, or of ascertaining the specific gravity to which they respectively correspond.

Table showing the Value of the Degrees of Baumé's Hydrometer in those of Cartier's.
